Abstract

Congenital Proopiomelanocortin deficiency (POMC) is a rare autosomal recessive disorder characterized by the association of adrenal insufficiency, early onset obesity, hyperphagia and altered skin & hair pigmentation. POMC is a complex propeptide encoding a range of melanocortin peptides that are released by tissue-specific proteolytic processing. These peptides have important roles in a range of functions such as skin pigmentation and the control of adrenal growth and function. In the central nervous system, POMC is most highly expressed in the arcuate nucleus of the hypothalamus, and POMC-expressing neurons are critically involved in the control of appetite and energy balance. We describe a novel homozygosity mutation for POMC gene in a Palestinian family with congenital POMC deficiency. A Palestinian

infant, born to consanguineous parents, presented with early onset obesity, hyperphagia, adrenal insufficiency, and red hair. Cortisol level was undetectable before and after stimulation, very low ACTH level. Congenital Proopiomelanocortin deficiency syndrome was suspected and confirmed by molecular testing. DNA sequencing of the POMC gene revealed a homozygous mutation c.296delG (p.G99AfsX59) in exon 3, while his father & mother are heterozygous. This mutation has been detected before as a compound heterozygous and as a disease causing mutation. To the best of our knowledge, this is the first description of this disease in a Palestinian family with molecular confirmation in a homozygous form, allowing accurate genetic counseling, early diagnosis of affected kindreds, early therapeutic interventions and avoiding complications.

Your next submission with Juniper Publishers will reach you the below assets

- Quality Editorial service
- Swift Peer Review
- Reprints availability
- E-prints Service
- Manuscript Podcast for convenient understanding
- Global attainment for your research
- Manuscript accessibility in different formats
(Pdf, E-pub, Full Text, Audio)
- Unceasing customer service
