## Abstract

Development of new lines in wheat and its evaluation under different planting dates is pre requisites for enhancing productivity on sustainable basis. An experiment was conducted at Cereal Crops Research Institute, Pirsabaq, Now shera Pakistan during 2013-14. The study was carried out to evaluate six wheat advanced lines (PR-103, PR-105, PR-106, PR-107, PR-108 and PR-109) on different planting dates (Oct. 25<sup>th</sup>, Nov. 5<sup>th</sup>, Nov. 15<sup>th</sup>, Nov. 25<sup>th</sup>, Dec. 5<sup>th</sup> and Dec.15<sup>th</sup>) to identify the most suitable planting time and judge their performance under late sowing in the central agro-ecological zone of Khyber Pukhtunkhwa (KP), Pakistan. The experiment was laid out in randomized complete block design with split-plot arrangement replicated thrice. Sowing dates effect was studied in main-plots and wheat advance lines in sub-plots. Data were recorded on days to heading, days to maturity, canopy temperature, chlorophyll content, plant height, spike length, spike lets spike<sup>-1</sup>, grains spike<sup>-1</sup>, lodging score (%), 1000-kernel weight, grain yield, biological yield and harvest index. Highly significant differences were found among planting dates. Days to heading, days to maturity, canopy temperature, chlorophyll content, plant height and spike length of various wheat advance lines were decreased to 17.6, 19, 11.1, 11.5 15 and 5% respectively when the sowing time was delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>. Spikelets spike<sup>-1</sup>, grains spike<sup>-1</sup>, 1000-grain weight, biomass yield, grain yield and harvest index of various wheat advance lines were also decreased to 7.5, 16, 26.7, 47.7, 35.2 and 19.2% respectively when sowing was delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>, while lodging score% were maximum on Nov. 5<sup>th</sup> and zero on Dec. 5<sup>th</sup>. Grain yield losses of 3.6, 9.9, 12.4, 19.4 and 35.2% were recorded on respective sowing dates and the percent yield losses were increased as sowing delayed from Oct. 25<sup>th</sup> till Dec. 15<sup>th</sup>. Significant differences were found among various wheat advance lines on days to heading, spike length, spike lets spike<sup>-1</sup>, grains spike<sup>-1</sup>, plant height, lodging score (%), 1000-kernel weight, biological yield while flag leaf area, days to maturity, canopy temperature, and chlorophyll content were not significantly affected. The interactive effects among various wheat advance lines and different sowing dates were not significant except spike lets spike<sup>-1</sup>. Among various wheat advance lines PR-107 produced higher grain yield (4803kg ha<sup>-1</sup>) followed by PR-106 and PR-103 while minimum grain yield (3847kg ha<sup>-1</sup>) were observed for PR-109 at all sowing dates. Among various sowing dates, Oct. 25<sup>th</sup> sown crop resulted statistically maximum grain yield (5196kg ha<sup>-1</sup>) followed by Nov. 05<sup>th</sup> sown crop (5008kg ha<sup>-1</sup>) against minimum grain yield (3366kg ha<sup>-1</sup>) of Dec. 15<sup>th</sup> sown crops. Average performance of wheat advance lines PR-107 and PR-103 on Oct. 25<sup>th</sup> and Nov. 5<sup>th</sup> sowing dates, were recorded (5537kg ha<sup>-1</sup>) and (5287kg ha<sup>-1</sup>) respectively. Greater average yield of PR-106 (5373kg ha<sup>-1</sup>) were recorded on Nov. 15<sup>th</sup> and Nov. 25<sup>th</sup> sowing dates. Thus, these results indicates that wheat advance lines should be sown on optimum sowing time Oct 25<sup>th</sup> and Nov. 05<sup>th</sup> for producing maximum grain yield in the central agro-ecological zone of Khyber Pukhtunkhwa (KP).

**Keywords:** Wheat (*Triticum aestivum* L) advance lines; Planting dates; Agronomic traits; Grain yield

## Introduction

Wheat (*Triticum aestivum* L) belongs to poaceae family, tribe hardene and genus triticum. In Pakistan it is called kanak (punjabi), ghanum (pushto), and gandum (urdu). Wheat is an annual, self pollinated and photo periodically long day plant. Wheat has four main parts including root, stem, leaves and inflorescence (spike). Wheat three groups diploids had 14(n=7), tetraploids had 28(n=14) and the hexaploids had 42(n=21) chromosomes. Wheat grain contains all essential nutrients; kernel contains about 12 percent water, including carbohydrates

(60-80% mainly as starch), proteins (8-15%) containing adequate amounts of all essential amino acids (except lysine, tryptophan and methionine), fats (1.5-2%), wheat is adapted to temperate regions from 30-60 °N and 27-40 °S latitudes.

Wheat is most important cereal crop for the majority of world's populations. It is the most important staple food of about two million people (36% of the world population) today wheat is grown all over the world, with different varieties sown according to the various climates the greatest portion of the wheat flour produced is used for bread making. Winter and spring wheat's

are the two major types of the crop, with the severity of the winter determining whether a winter or spring type is cultivated.

It is important food crop of Pakistan grown during the winter season. It is being eaten through out the country daily three times. Wheat crop occupies a central position in forming agricultural policies and dominates all crops in acreage and production. Demand for wheat in the country is increasing day by day. The greatest demand for wheat in the coming years will have to be met by increasing devotion of land to wheat and or increasing yield per unit area. In 2012-13, wheat grown in Pakistan on an area of 8693 thousand hectare with total production of 24231 thousand tons, making an average yield of 2786kg per hectare (Pakistan economic survey 2012-13).

Low yield of wheat in Khyber Pakhtunkhwa and Pakistan as a whole is attributed to various factors such as planting date is one of the major factors which determine the ability of the crop to stand against different environmental conditions (air, temperature and humidity). Appropriate sowing date is important to have the crop in the field, when environmental conditions are conducive for growth and development. Variation in weather conditions among and within seasons is one of the most important constraints affecting yield potential [1]. Therefore one of the requirements for obtaining high yield is the choice of the suitable sowing date due to variations in weather conditions among seasons and developing new high yielding cultivars and by adopting proper sowing date. One of the most important factors influencing the wheat yield is sowing time. Many researchers have carried out some studies on sowing times of wheat and found different results [2,3].

Wheat is sown in winter and it has its own definite requirements for temperature and light for emergence, growth and flowering [4]. Early sowing always produces higher yield than late sowing. Early sown wheat had higher grain yield Qamar et al. [5]. The detrimental effect of delayed sowing on grain yield was maximum with reduction in 1000-kernel weight [5,6].

Delayed sowing also significantly reduced test weight [7]. High temperature and desiccating winds during the month of April might cause forced maturity of late sown wheat, thus resulting in reduction of test weight [8]. Higher grain crude protein content but lower grain sizes were obtained with delayed sowing [9]. High temperature in the post anthesis period of late sown wheat shortened the grain filling period resulting in a smaller endosperm, lower grain weight and increased protein content [10]. Subhan et al. [11] and Qasim et al. [12] concluded that crop planted on November 15, produced higher grain yield as compared to late and early planting. However, mid-season sowing of winter wheat for any locality is usually most favourable. When optimum condition was provided by the wheat cultivar, grain filling period was higher as compared to late sown condition under high temperature stress at maturity.

Cereal Crops Research Institute (CCRI), Pirsabak Nowshera (KPK) Pakistan has the mandate to produce wheat varieties

suitable for normal and late planting in rainfed and irrigated areas of the province. Every year, the promising lines are tested in a sowing dates trial to record their yield performance in various sowing dates and later on make recommendations for these prospective wheat varieties for normal and/or late planting in various parts of KP. The present project is therefore, designed with the objectives to find out the performance of different wheat (*Triticum aestivum* L.) advance lines (PR-103, PR-105, PR-106, PR-107, PR-108 and PR-109) for agronomic traits and grain yield under different sowing dates (Oct. 25<sup>th</sup>, Nov. 5<sup>th</sup>, Nov. 15<sup>th</sup>, Nov. 25<sup>th</sup>, Dec. 5<sup>th</sup> and Dec.15<sup>th</sup>).

### Materials and Methods

The experiment was conducted at Cereal Crops Research Institute, Pirsabak Nowshera, Khyber Pakhtunkhwa, Pakistan during 2013-14. The experimental site located at 32 °N Latitude, 74 °E Longitude and 288m Altitude. The soil type of experimental site was sandy loam having a pH range from 7 to 8. Six newly developed wheat advance lines (PR-103, PR-105, PR-106, PR-107, PR-108 and PR-109) were planted on six different sowing dates (Oct. 25<sup>th</sup>, Nov. 5<sup>th</sup>, Nov. 15<sup>th</sup>, Nov. 25<sup>th</sup>, Dec. 5<sup>th</sup> and Dec. 15<sup>th</sup>) in a randomized complete block design with split plot arrangement repeated thrice. Each entry was grown in six rows of five meters long with row to row distance of 30cm. Plot area was 9m<sup>2</sup>. Uniform seed rate of 100kg per hectare was used. Planting was done with hand hoe. Fertilizer was applied at the ratio of 120:60kg per hectare of N:P in the form of Urea and Single Super Phosphate (SSP). SSP was applied as basal dose at the time of sowing while urea was applied in split doses; half at the time of sowing and half with first irrigation. All other recommended and standard agronomic practices were kept normal and uniform for all the experimental units in order to reduce experimental error. Data were recorded from central four rows in each subplot.

### Statistical Analysis

Data were analyzed statistically with the statistical package MSTAT-C (Knowledge Dynamics Corporation, USA). The ANOVA test was used to determine significant ( $p \leq 0.01$  or  $p \leq 0.05$ ) treatment effect. LSD test was also applied for the significance of treatment differences.

### Results and Discussion

#### Days to 50% heading

Mean results (Table 1) showed that significant differences for days to 50% heading of various wheat advance lines sown at different dates. Maximum number of days to 50% heading (130 days) were recorded for Oct. 25<sup>th</sup> sown crop. Days to 50% heading decreased gradually (107 days) as sowing was delayed from Oct. 25<sup>th</sup> till Dec. 15<sup>th</sup>. Similar finding were also reported by Khan et al. [14] stated that growing crops at different sowing dates pass through each development stage under different environmental conditions. There was no significant difference of days to 50% heading among wheat lines except PR-109, took minimum days to heading as compared to PR-107 and PR-106.

However, as the time passed, differences between wheat advance lines became prominent. Minimum number of days (107, 107 and 108 days) was recorded for wheat lines PR- 103, PR-105 and PR-106 showing decrease 18.3, 17 and 19.4% respectively while PR-107, PR-108 and PR-109 took 108, 106 and 105 days,

showing decrease 19, 15.8 and 16% respectively in days to 50% heading, when wheat lines were sown on Oct. 25<sup>th</sup> as compared to Dec. 15<sup>th</sup> (Table 1). Wheat is sown in winter and it has its own definite requirements for temperature and light for emergence, growth and days to 50% heading.

**Table 1:** Mean values for days to 50% heading of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	131ab	131ab	122d-h	119h-k	114i-m	107p	121b
PR-105	129bc	130bc	122e-h	117i-l	116k-m	107p	120bc
PR-106	134a	132ab	124d-g	120g-j	113mn	108op	122a
PR-107	134a	133a	125d-f	121g-i	114l-m	108op	123a
PR-108	126cd	131ab	121f-h	117j-m	114i-m	106p	119c
PR-109	125de	124d-g	117j-m	116k-m	111no	105p	116d
Mean	130a	130a	122b	118c	114d	107e	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 1.96 LSD (wheat advance lines): 1.40 LSD (sowing dates x wheat advance lines): 3.43.

### Days to physiological maturity

**Table 2:** Mean values for days to physiological maturity of developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Nov. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	175a	171d-e	166fg	159hi	149j	142k	160.3ab
PR-105	174a-c	172b-e	167f	159hi	149j	140kl	160.3ab
PR-106	174a-c	172c-e	166fg	158i	149j	141kl	160.1ab
PR-107	175ab	174a-c	164g	160h	149j	142k	160.7a
PR-108	172c-e	171e	167f	159hi	148j	140kl	159.6b
PR-109	174a-c	172c-e	167f	158hi	149j	139l	159.9ab
Mean	174a	172b	166c	159d	149e	141f	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 1.05 LSD (wheat advance lines): 0.97 LSD (sowing dates x wheat advance lines): 2.38.

Mean results (Table 2) revealed that significant affect on days to physiological maturity of various wheat advance lines sown at different dates. Maximum number of days to maturity (174 days) was recorded for Oct. 25<sup>th</sup> sown crop. Days to maturity decreased (141 days) gradually as sowing was delayed till Dec. 5<sup>th</sup>. Subhan et al. [15] also reported decrease in days to maturity due to delay in sowing in the central agro-ecological zone of KP Pakistan. There was no significant difference of days to physiological maturity among various wheat advance lines. However, as the time passed, differences between wheat advance lines became prominent. Minimum number of days 142, 140 and 141 were recorded for wheat lines PR-103, PR-105, and PR-106 showing decrease 18.8, 19.5 and 18.9% respectively while PR-107, PR-108 and PR-109 were recorded 142, 140 and 139 days showing

decrease 18.8, 18.6 and 19.4% respectively in days to maturity, when wheat lines were sown on Oct. 25<sup>th</sup> as compared to Dec. 15<sup>th</sup> (Table 2). Such wheat lines, if high yielding, are the most suitable for KP zone.

### Canopy temperature at post anthesis stage (°C)

Mean results (Table 3) revealed that significant affect on canopy temperature at post anthesis stage of various wheat advance lines sown at different dates. Maximum canopy temperature at post anthesis stage (24.4 °C) was recorded for Dec. 15<sup>th</sup> sown crop while minimum (21 °C) was recorded for Nov. 5<sup>th</sup> sown crop. There was no significant difference of canopy temperature at post anthesis stage among various wheat advance lines. Differences between wheat advance lines became

prominent with passage of time. Mean canopy temperature (21.4 °C) at post anthesis stage was recorded for Oct. sown crop in wheat lines PR-103, PR-105, and PR-106 showing increase 11.4, 11.2 and 10% respectively while (21.4 °C) was recorded for PR-107, PR-108 and PR-109 showing increase 11.6, 11.3 and 11.1% respectively over Dec. 15<sup>th</sup> sown crop.

**Table 3:** Mean values for canopy temperature (°C) at post anthesis stage of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	21.6e-i	21.3f-j	21.0h-j	22.3d-h	24.4a	24.4a	22.5a
PR-105	21.4f-j	21.1h-j	22.2d-h	22.4d-h	24.4a	24.8a	22.7a
PR-106	21.2f-j	20.1j	21.8e-i	23.4a-d	24.1ab	24.2ab	22.5a
PR-107	21.8e-i	21.0h-j	22.5d-g	22.6c-f	24.0a-c	24.5a	22.8a
PR-108	21.4f-j	20.7i-j	21.7e-i	21.4f-j	24.3a	24.1ab	22.3a
PR-109	21.2f-j	21.8e-i	21.1h-j	22.9b-e	23.5a-d	24.5a	22.5a
Mean	21.4cd	21.0d	21.7c	22.5b	24.1a	24.4a	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 0.67 LSD (wheat advance lines): 0.57 LSD (sowing dates x wheat advance lines): 1.41.

### Chlorophyll content at post anthesis stage (mg)

**Table 4:** Mean values for chlorophyll content (mg) at post anthesis stage of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	44.5a-e	43.9a-f	46.2ab	41.9a-g	42.7a-g	37.7g	42.8a
PR-105	42.6a-g	43.5a-g	42.6a-g	41.4a-g	41.3a-g	39.5d-g	41.7a
PR-106	47.2a	44.1a-f	41.4a-g	40.3b-g	44.5a-e	38.1fg	42.6a
PR-107	44.9a-d	43.2a-g	40.9b-g	41.0b-g	42.6a-g	38.2fg	41.1a
PR-108	43.4-ag	44.0a-f	41.6a-g	41.2a-g	40.7b-g	40.1b-g	41.8a
PR-109	45.1a-c	38.5e-g	39.4e-g	43.1a-g	40.4b-g	42.8a-g	41.5a
Mean	44.6a	42.8ab	42.0b	41.5b	42.1b	39.0c	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 1.77 LSD (wheat advance lines): 2.59 LSD (sowing dates x wheat advance lines): 6.12.

After computing mean results (Table 4) significant affect on chlorophyll content at post anthesis of various wheat advance lines sown at different dates. Maximum chlorophyll content at post anthesis stage (44.6mg) was recorded for Oct. 25<sup>th</sup> sown crop and minimum chlorophyll content (39mg) was recorded for Dec. 15<sup>th</sup> sown crop. There was no significant difference of chlorophyll content at post anthesis stage among various wheat advance lines. Differences between wheat advance lines became prominent with passage of time. Chlorophyll content 44.5, 42.6 and 47.2mg at post anthesis stage was recorded for Oct. sown crop in wheat lines PR- 103, PR-105 and PR-106 showing 15.2, 7.2 and 18.2% decrease respectively while 44.9, 43.4 and 45.1 mg was recorded for PR-107, PR-108 and PR-109 showing 14.9, 7.6 and 5% decrease respectively over Dec. 15<sup>th</sup> sown crop.

### Flag Leaf Area (Cm<sup>2</sup>)

Mean results (Table 5) showed that flag leaf area was significantly decreased as planting delay. There were also significant differences among wheat lines for flag leaf area. Maximum flag leaf area (39.9cm<sup>2</sup>) was recorded for Nov. 5<sup>th</sup> sown crop across all sowing dates, while significantly minimum flag leaf area (30cm) was recorded for Dec. 15<sup>th</sup> sown crop due delayed planting. Maximum flag leaf area (37.3cm<sup>2</sup>) was recorded for wheat line PR-108 while minimum flag leaf area (33.8cm) was recorded for PR-107 at all sowing date. Flag leaf area was decreased from 9 to 20% respectively when planting delayed from Oct. 25<sup>th</sup> to Dec 15<sup>th</sup>. Elevation in temperature accelerates plant development while declined growth rate showed decline

in leaf size and spike size which ultimately resulted in low yield [16]. The significant interaction between genotype and sowing dates shows the sensitivity of different genotypes to photoperiod and temperature differently for flag leaf area.

**Table 5:** Mean values for flag leaf area (cm<sup>2</sup>) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013 -14.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR103	39.5a-c	39.4a-d	35.2b-h	34.1c-j	30.2h-k	30.4h-k	34.8b
PR105	37.9a-e	39.3a-d	41.0a	36.5a-g	32.3f-k	28.6jk	35.9ab
PR106	33.9d-k	39.0a-d	34.1c-j	34.8b-i	30.0h-k	30.8h-k	33.8b
PR107	35.3b-h	41.2a	37.0a-g	37.5a-f	29.4i-k	30.2h-k	35.1ab
PR108	40.0ab	41.3a	41.2a	39.1a-d	30.8h-k	31.4g-k	37.3a
PR109	34.7b-i	38.8a-d	39.0a-d	35.2b-h	32.8e-k	28.k	34.8b
Mean	36.9b	39.9a	37.9ab	36.2b	30.9c	30.0c	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 2.60 LSD (wheat advance lines): 2.22 LSD (sowing dates x wheat advance lines): 5.44.

### Spike Length (Cm)

**Table 6:** Mean values for spike length (cm) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	10.8g-j	10.8g-j	10.3d-h	12.7ab	10.9g-j	10.4c-f	11.1a
PR-105	10.0d	9.7h-m	10.4d-h	12.4ab	10.4d-h	9.9h-m	10.4b
PR-106	9.3n	9.8h-m	10.2d-h	10.8g-j	10.0d	9.3n	9.9b
PR-107	10.5c-f	10.4d-h	9.8h-m	11.3ab	10.3d-h	9.3n	10.3b
PR-108	10.6c-f	11.0a-c	10.6c-f	13.0a	10.5c-f	9.8h-m	10.9b
PR-109	9.4i-n	10.2d-h	10.2d-h	11.8ab	9.8h-m	10.1d	10.2b
Mean	10.8a	10.3bc	10.2bc	12.0a	10.8a	9.7c	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 0.52 LSD (wheat advance lines): 0.37 LSD (sowing dates x wheat advance lines): 0.91.

Mean results (Table 6) revealed that significant differences for spike length of various wheat advance lines sown at different dates. Spike length was significantly decreased from 10.8cm to 9.7cm when planting delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>. Maximum spike length (11.1cm) was produced for wheat line PR-103 while minimum spikes length (9.9cm) was produced for PR-106 at all sowing dates. Spike length ranged from 9.3cm to 10.8cm for all genotypes decreased from 3 to 7% respectively when wheat lines were sown from Oct. 25<sup>th</sup> to delay till Dec. 15<sup>th</sup>. There was no significant difference of spike length among various wheat advance lines except PR-106 which have 9.9cm spike length as compare to PR-103 (11.1cm) at all sowing dates. The spike length probably decreased due to delay in sowing because of the sensitivity of the wheat plants to photoperiod and temperature [17]. As the photoperiod and temperature increased, the wheat plants hastened maturity to complete growth period due to

which the plant parameters, like plant height and spike length got shorter period to increase in size. Slafer [18] have suggested that there is a strong interaction between the responses to temperature and photoperiod in terms of various plant parameters and that the size of interaction may different among genotypes. The significant interaction between genotype and sowing dates for spike length signifies the sensitivity of different genotypes to photoperiod and temperature differently and, thus, confirms the suggestions of Slafer [18].

### Spikelets Spike-1

Mean results (Table 7) showed that significant differences for spikelets spike<sup>-1</sup> of various wheat advance lines sown at different dates. Spikelets spike<sup>-1</sup> was significantly decreased from 17.2 to (15.9) when planting was delayed from Oct. 25<sup>th</sup> to Dec.

15<sup>th</sup>. Maximum number of spikelets spike<sup>-1</sup> (18.8) was produce for wheat line PR-103 which was not significantly different from that of PR-107 and PR-105, while minimum number of spikelets spike<sup>-1</sup> (16.6) was produce for PR-109 at all sowing dates. The number of spikelets spike<sup>-1</sup> probably decreased with delay in planting date because of reduction in spike length. The decrease was significant when planting was delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>; it decreased to 7.5% respectively. According

to Shafiq [19] early sowing enhanced spikelets spike<sup>-1</sup> over late sowing. There was no significant difference of spikelets spike<sup>-1</sup> among various wheat advance lines except PR-109 which have less number (16.6) and significantly effected as compare to other wheat advance lines. The number of spikelets spike<sup>-1</sup> probably decreased because of reduction in spike length, although it is not necessary because in lax spikes, the number of spikelets spike<sup>-1</sup> is small and it is the characteristic of some varieties [20].

**Table 7:** Mean values for spikelets spike<sup>-1</sup> of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	16.7e-h	19.7ab	19.0a-c	17.7c-g	16.7e-h	17.4c-h	18.8ab
PR-105	18.7b-d	18.3b-e	18.0b-f	18.0b-e	17.3c-h	16.0gh	17.7ab
PR-106	17.0c-h	18.3b-e	18.0b-f	18.3b-e	16.3f-h	16.0gh	17.3b
PR-107	18.3b-e	20.7a	19.7ab	17.7c-g	17.0c-h	17.0c-h	18.4a
PR-108	16.3f-h	18.0b-f	18.3b-e	19.0a-c	16.3f-h	15.7h	17.3b
PR-109	16.6e-h	17.0c-h	17.7c-g	17.7c-g	16.7e-h	13.7i	16.6b
Mean	17.2bc	18.7a	18.4a	18.1bc	16.7cd	15.9d	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 0.93 LSD (wheat advance lines): 0.68 LSD (sowing dates x wheat advance lines): 1.67.

### Number of Grains Spike<sup>-1</sup>

**Table 8:** Mean values for number of grains spike<sup>-1</sup> of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	65.3a-d	66.7a-c	64.3a-e	65.7a-d	57.3e-f	56.0f-i	57.6a
PR-105	66.7a-c	67.7ab	71.0a	63.7b-e	59.0d-e	55.0g-i	57.4a
PR-106	56.0f-i	61.3c-e	61.0c-e	64.0a-e	56.3f-i	55.0g-i	56.3ab
PR-107	59.7d-e	68.0ab	66.3a-c	63.0b-e	62.3b-e	52.2hi	55.4ab
PR-108	57.0e-f	67.3ab	68.7ab	65.7a-d	59.0d-e	55.3g-i	54.3bc
PR-109	59.3d-e	59.7d-e	59.0d-e	62.0b-e	57.7e-f	48.7i	53.3c
Mean	60.7ab	65.1a	65.1a	64.0a	58.6ab	53.8b	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 4.83 LSD (wheat advance lines): 3.44 LSD (sowing dates x wheat advance lines): 8.44.

Mean results (Table 8) showed that significant differences for grains spike<sup>-1</sup> of various wheat advance lines sown at different dates. Number of grains spike<sup>-1</sup> was significantly decreased from (60.7) to (53.8) when wheat lines were delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>. Maximum number of grains spike<sup>-1</sup> (65.3, 66.7, 59.7 and 59.3) was produced for wheat lines PR-103, PR-105, PR-107 and PR-109 showing decrease 14.8, 14.2, 17.5 and 17.8% respectively when planting was delayed from Oct. 25<sup>th</sup> to Dec.15<sup>th</sup>. There was no significant difference between PR-106 and PR-108 at planting dates. These findings are supported by those of Hanson [21], who reported significant variation in

number of grains spike<sup>-1</sup> with sowing dates. Maximum number of grain spike<sup>-1</sup> (57.6) was produced for wheat line PR-103 while minimum number grains spike<sup>-1</sup> (53.3) was produced for PR-109 at all sowing dates. Less number of grains spike<sup>-1</sup> in late sowing was due to less production of photosynthesis due to shorter growing period. These results are in line with those of Shahzad et al. [21]. Differences in number of grains spike<sup>-1</sup> among wheat lines might be attributed to their genetic variability. These results are in line with those reported by Haider [22]. The grains spike<sup>-1</sup> seemed to have decreased due to delay in sowing because of the sensitivity of the wheat plants to photoperiod and temperature.

### Plant Height (Cm)

**Table 9:** Mean values for plant height (cm) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Wheat Lines	Sowing Dates						Mean
	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	
PR-103	120a	117a-c	115a-e	107g-l	113b-g	99m-q	112a
PR-105	115a-d	105i-o	108e-j	105c-i	192j-q	96pq	105d
PR-106	118ab	114a-f	114b-g	111c-i	107f-l	98o-q	110ab
PR-107	116a-d	110c-i	112b-h	108e-j	105h-n	101k-q	109bc
PR-108	113b-g	108e-j	107g-l	109d-j	103j-p	101-q	107cd
PR-109	111c-i	108e-j	106h-m	99n-q	108f-k	97q	105d
Mean	116a	110b	110b	107c	107c	99d	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 3.02 LSD (wheat advance lines): 2.81 LSD (sowing dates x wheat advance lines): 6.89.

On average results (Table 9) revealed that plant height was significantly decreased as planting delay. There were also significant differences among the wheat advance lines for plant height. Maximum plant height (116cm) was recorded for Oct sown crop across all sowing dates while minimum plant height (99cm) was recorded over Dec. 15<sup>th</sup> sown crop, which was significantly different. Maximum plant height (112cm) was recorded for wheat lines PR-103 and minimum plant height (105cm) was recorded for PR-109 at all sowing date. Plant height

was decreased from 11 to 19% respectively when wheat lines were delayed from Oct. 25<sup>th</sup> to Dec 15<sup>th</sup>. Decrease in plant height in late sowing was due to shorter growing period. Early sown crop may have enjoyed the better environmental conditions especially the temperature and solar radiation which resulted to tallest plants. These results are in line with those reported by Shahzad et al. [21]. Differences in plant height among varieties might be attributed to their genetic diversity. These results are similar to those of Ahmad et al. [23].

### Lodging Score (%)

**Table 10:** Mean values for lodging score (%) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Wheat Lines	Sowing Dates						Mean
	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	
PR-103	7c-d	11b-d	7c-d	0d	0d	0d	4bc
PR-105	1d	2d	5cd	0d	0d	0d	1c
PR-106	5cd	41a	29ab	2d	6cd	0d	14a
PR-107	3d	25a-c	18b-d	12b-d	1d	0d	10ab
PR-108	1d	2d	7c-d	4d	0d	0d	2c
PR-109	0d	15b-d	5cd	0d	14b-d	0d	6bc
Mean	3ab	16a	12ab	3ab	4ab	0b	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 13.47 LSD (wheat advance lines): 6.69 LSD (sowing dates x wheat advance lines): 16.39.

Mean results (Table 10) showed that lodging score (%) was not significantly decreased as planting delay. There were significant differences among the wheat advance lines for lodging score (%). The maximum lodging score (16%) was recorded for Nov. 05<sup>th</sup> sown crop, this lodging score was highest across all sowing dates while minimum lodging score (0%) was recorded for Dec. 15<sup>th</sup> sown crop. The excessive rains and downpours in the growing season caused lodging on Nov. 05<sup>th</sup>. Maximum lodging score (14%) was recorded for wheat line PR-

106 and minimum lodging score (1%) was recorded for PR-105 at all planting dates. Lodging score were decreased to (0%) with delay in planting date.

### Biomass Yield (Kg Ha<sup>-1</sup>)

Mean results (Table 11) showed that biomass yield (kg ha<sup>-1</sup>) was significantly decreased as planting delay. There were also significant differences among the wheat lines for biomass yield. Maximum biomass yield (19517kg ha<sup>-1</sup>) was recorded

for Oct. 25<sup>th</sup> sown crop across all sowing dates, while minimum biomass yield (9820kg ha<sup>-1</sup>) was recorded for Dec. 15<sup>th</sup> sown crop, which was significantly different due to delay in sowing time. Among time of sowing, significant maximum biomass yield was recorded (19517kg ha<sup>-1</sup>) and (18548kg ha<sup>-1</sup>) for Oct 25<sup>th</sup> and Nov. 05<sup>th</sup> sown crop against minimum biomass yield (9820kg ha<sup>-1</sup>) for Dec. 15<sup>th</sup> sown crop. Average performance of wheat lines PR-107 and PR-106 were recorded (20100kg ha<sup>-1</sup>) and (19646kg ha<sup>-1</sup>) followed by PR-103 (18999kg ha<sup>-1</sup>), while PR-105 produce the lowest biomass yield (17998kg ha<sup>-1</sup>), when wheat lines were sown on Oct. 25<sup>th</sup> and Nov. 5<sup>th</sup>. Maximum biomass yield (16651kg ha<sup>-1</sup>) was recorded for wheat lines PR-106 and followed by PR-107 (15939kg ha<sup>-1</sup>), while minimum biomass yield (14095kg ha<sup>-1</sup>) was recorded for PR-109 at all sowing dates. Biomass yield decreased gradually and significantly in all wheat advance lines with delay in sowing time. Yield losses due to late planting were

recorded 4.9% when planting was done on Nov. 5<sup>th</sup>, 11.1% when planting was done on Nov.15, 17.6% when planting was done on Nov. 25<sup>th</sup>, 25.4% when planting was done on Dec. 5<sup>th</sup> and 49.6% when planting was further delayed till Dec. 15<sup>th</sup> as compare to Oct. 25<sup>th</sup>. These findings are in agreements with those of Wajjid [24], who also reported that early planting increases biomass yield while late planting decreases biomass yield. Biomass yield decreased from 43.2 to 49.6% when wheat lines were delayed from Oct. 25<sup>th</sup> to Dec. 25<sup>th</sup>. The first reason may be more suitable climatic condition for maximum vegetative and reproductive components resulted increased biomass yield. Secondly it may be due to reproductive plants unit per area. In later sowing date's biomass and grain yield decreased due to undesired environmental conditions and lack of suitable transforming preserved matters to seeds as a result of increasing temperature at the end of growth season.

**Table 11:** Mean values for biomass yield (kg ha<sup>-1</sup>) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean

PR-109	20332ab	16813e-i	16962c-h	16369d-i	12925jl	7406m	14095c
Mean	19517a	18548ab	17344b	16067c	14548d	9820e	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 1.08 LSD (wheat advance lines): 0.93 LSD (sowing dates x wheat advance lines): 2.29.

### 1000-Kernel Weight (G)

**Table 12:** Mean values for 1000-kernel weight (g) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Sowing Dates							
Wheat Lines	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec.15	Mean
PR-103	53.4a-c	49.2b-f	48.3b-g	44.0c-g	43.3c-g	39.5fg	46.3cd
PR-105	49.1b-f	47.0b-g	43.2c-g	42.1d-g	41.5d-g	37.9g	43.5d
PR-106	51.1a-e	47.1b-g	47.2b-g	46.4b-g	44.6c-g	39.8fg	46.0cd
PR-107	53.0a-c	53.3a-c	50.7a-e	48.5b-g	48.0b-g	43.7c-g	49.5ab
PR-108	60.7a	56.6ab	51.6a-d	49.7b-f	42.1d-g	41.7d-g	50.4a
PR-109	54.0a-c	49.1b-f	49.1b-f	44.6c-g	47.4b-g	40.6e-g	47.5bc
Mean	53.5a	50.4ab	48.3bc	45.9c	44.5cd	40.5d	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 2.74 LSD (wheat advance lines): 1.97 LSD (sowing dates x wheat advance lines): 4.83.

Mean results (Table 12) revealed that 1000-kernel weight was significantly decreased as planting delay. 1000-kernel weight ranged from 49.1g (PR-105) to 60.7g (PR-108), for

Oct. 25<sup>th</sup> sown crop. As planting delayed, 1000-kernel weight gradually decreased for all wheat advance lines and kernel weight loss continued till Dec. 15<sup>th</sup>. Differences between wheat

advance lines became prominent with passage of sowing time. The 1000-kernel of wheat lines PR-103, PR-105, PR-106, PR-107, PR-108 and PR-109 were decreased from range of 22.2 to 31.3% respectively when planting was delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>. Maximum 1000-kernel weight (50.4g) was recorded for PR-108 and minimum 1000-kernel weight (43.5g) was recorded for PR-105 at all sowing date. 1000-kernel weight is not related with grains per spike in different genotypes. For example, maximum 1000-kernel weight for PR-108 but minimum grains per spike. It shows that genotype strongly affects the grain size. These findings are in line with those of [25] who observed the effect of different sowing times on 1000-kernel weight of wheat. The

reasons may be genetic make-up of the genotypes or less/more competition for plant nutrients which produced weak/healthy plants and turn into healthier and plump seed formation. The early sowing resulted in better development of the grains due to longer growing period. These findings are strongly supported by those of Spink et al. [26] and Shahzad et al. [21] who had also reported decreased 1000-kernel weight with delay in sowing. Dokuyucu et al. [2] reported significant decreases in grain weight on the earlier and later sowing dates. Differences in 1000-kernel weight among varieties might be attributed to their genetic diversity. These results are in line with those of Shahzad et al. [21].

### Harvest Index (%)

**Table 13:** Mean values for harvest index (%) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Wheat Lines	Sowing Dates						Mean
	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec. 15	
PR103	28.3d-g	27.2d-g	26.9d-g	28.9c-g	30.4a-f	33.9a	29.3a
PR105	30.0b-f	26.6d-g	26.3d-g	31.7a-e	32.6a-d	33.3a-c	30.1a
PR106	24.7fg	29.1c-g	28.6d-g	31.2a-f	26.3d-g	32.8b-f	28.8a
PR107	26.3d-g	28.3d-g	25.9d-g	29.0c-g	31.6a-e	33.8ab	29.2a
PR108	26.5d-g	27.8d-g	30.0b-f	29.1c-g	25.9d-g	32.7a-d	28.6ab
PR109	25.1e-g	22.7g	25.5e-g	22.6g	26.4d-g	32.7a-d	25.8b
Mean	26.8b	26.9b	27.2b	28.8b	28.9b	33.2a	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 3.12 LSD (wheat advance lines): 2.72 LSD (sowing dates x wheat advance lines): 6.67.

Mean results (Table 13) showed that significant differences for harvest index (%) of various wheat advance lines sown at different dates. Maximum harvest index (33.2%) was recorded for Dec. 15<sup>th</sup> sown crop across all sowing dates while the minimum harvest index (26.8%) was recorded for Oct. 25<sup>th</sup> sown crop. There were significant differences among the wheat advance lines for harvest index (%). Minimum harvest index (25.8%)

was recorded for wheat line PR-109 and maximum harvest index (30.1%) was recorded for PR-105 at all sowing dates. The interaction of wheat lines and sowing date for harvest Index (%) was not significant. Harvest index was increased (19.2%) for Oct. 25<sup>th</sup> sown crop as compare to Dec 25<sup>th</sup>. The contrasting results reported by Wajjid [24], who observed that both early and delay planting affect harvest index significantly.

### Grain Yield (Kg Ha<sup>-1</sup>)

**Table 14:** Mean values for grain yield (kg ha<sup>-1</sup>) of newly developed wheat advance lines planted on different sowing dates evaluated at CCRI Pirsabak during 2013-2014.

Wheat Lines	Sowing Dates						Mean
	Oct. 25	Nov. 5	Nov. 15	Nov. 25	Dec. 5	Dec. 15	
PR103	5231a-f	5344a-e	4609d-k	4737a-h	4361f-m	3544m-q	4637a
PR105	5496a-c	4685c-j	4279h-n	4699a-h	4755b-i	3432n-q	4599ab
PR106	4748b-j	5662a	5474a-c	5273a-d	4013i-o	3633l-q	4800a
PR107	5466a-d	5608ab	4605d-k	4727e-l	4744b-j	3668l-q	4803a
PR108	5174a-g	4927a-h	4783a-i	4187j-p	3922i-p	3031pq	4341b
PR109	5059a-h	3823k-p	4327g-m	3673l-q	3327o-q	2870q	3847c
Mean	5196a	5008ab	4679b	4549bc	4187c	3366d	

Means in the same category following by different letters are significantly different from each other at 5% level of probability. LSD (sowing dates): 4.33 LSD (wheat advance lines): 3.44 LSD (sowing dates x wheat advance lines): 8.44.

Mean results (Table 14) showed grain yield ( $\text{kg ha}^{-1}$ ) was significantly decreased as planting delayed. Maximum grain yield ( $5196\text{kg ha}^{-1}$ ) was recorded for Oct. 25<sup>th</sup> sown crop which decreased significantly to ( $3366\text{kg ha}^{-1}$ ) for Dec. 15<sup>th</sup> sown crop. Among time of sowing, significant maximum grain yield was recorded ( $5196\text{kg ha}^{-1}$ ) and ( $5008\text{kg ha}^{-1}$ ) for Oct. 25<sup>th</sup> and Nov. 05<sup>th</sup> against minimum grain yield ( $3366\text{kg ha}^{-1}$ ) for Dec. 15<sup>th</sup> sown crop. Thus, wheat advance lines should be preferably sown on Oct 25<sup>th</sup> and Nov. 05<sup>th</sup> as optimum sowing time for maximum grain yield in KP zone. Average performance of wheat lines PR-107 and PR-103 were recorded ( $5537\text{kg ha}^{-1}$ ) and ( $5287\text{kg ha}^{-1}$ ) followed by PR-106 ( $5208\text{kg ha}^{-1}$ ), while PR-109 produce lowest grain yield ( $4441\text{kg ha}^{-1}$ ), when wheat lines were sown on Oct. 25<sup>th</sup> and Nov. 5<sup>th</sup>. Averaged performance of wheat lines PR-107 and PR-106 produce highest grain yield ( $4803\text{kg ha}^{-1}$ ), ( $4800\text{kg ha}^{-1}$ ) followed by PR-103. while PR-109 produce the lowest grain yield ( $3847\text{kg ha}^{-1}$ ) at all sowing dates. This may be attributed to the smaller number of grains spike<sup>-1</sup>, spikelets spike<sup>-1</sup>, lower biomass yield and smaller grain size. Therefore, wheat lines PR-107 and PR-106 produce higher grain yield at all planting dates as these lines has been released in future for normal and late sowing in irrigated areas of KP zone. Grain yield decreased significantly in all wheat advance lines with delay in sowing time. The percent decreased in wheat lines from Oct. 25<sup>th</sup> to delayed till Dec. 15<sup>th</sup> sown crop were 32.2% in PR-103, 37.5% in PR-105, 23.4% in PR 106, 32.8% in PR-107, 41.4% in PR-108 and 43.2% respectively in PR-109. Grain yield losses due to late planting were recorded 3.6% when planting was done on Nov. 5<sup>th</sup>, 9.9% when planting was done on Nov. 15<sup>th</sup>, 12.4% when planting was done on Nov. 25<sup>th</sup> and 19.4% when planting was done on Dec. 5<sup>th</sup> and 35.2% respectively when planting was further delayed till Dec. 15<sup>th</sup>. These results are in line with those [27-30] who reported that sowing times and varieties of wheat both significantly effect on grain yield. Decrease in the yield attributes i.e. spike length spikelets spike<sup>-1</sup> number grains spike<sup>-1</sup> and 1000-kernel weight due to delay in sowing contributed to decrease in the grain yield for which the main reasons are the decrease in growing degree days [31-35], longer photoperiod and higher temperature during the reproductive stage and the genotype. The yield attributes studied in this experiment showed smaller decrease 11.3% in number of grains spike<sup>-1</sup> and 24.2% in 1000-kernel weight as compared with the 35.2% decreased in the grain yield when sowing was delayed from Oct. 25<sup>th</sup> to Dec. 15<sup>th</sup>. It shows that the rest of the decreased in grain yield might be due to decrease in the number of productive tillers per unit area. In later sowing date's biomass and grain yield decreased due to undesired environmental conditions and lack of suitable transforming preserved matters to seeds as a result of increasing temperature at the end of growth season [36-38].

## Conclusion

It is concluded from the results of the experiment that sowing in time around from Oct. 25<sup>th</sup> to Nov. 05<sup>th</sup> in central KP is suitable for policy for getting higher grain yields and even the wheat

advance lines cannot be recommended for late sowing due to yield losses in delay sowing. Significant differences exist among wheat advance lines in maturity duration. So breeders should select those genotypes, which could compensate up to large extent, although it may not recover fully, yield losses due to delay in sowing. Among different sowing dates, significant maximum grain yield was recorded ( $5196\text{kg ha}^{-1}$ ) and ( $5008\text{kg ha}^{-1}$ ) for Oct 25<sup>th</sup> and Nov. 05<sup>th</sup> against the minimum grain yield of ( $3366\text{kg ha}^{-1}$ ) for Dec. 5<sup>th</sup> sown crop, we recommend that all wheat advance lines may be preferably sown on Oct 25<sup>th</sup> to Nov. 05<sup>th</sup>, indicating optimum sowing time for producing maximum grain yield in KP zone [39]. Wheat advance lines PR-107 and PR-103 sown on Oct. 25<sup>th</sup> and Nov. 5<sup>th</sup> resulted maximum grain yield recorded ( $5537\text{kg ha}^{-1}$ ) and ( $5287\text{kg ha}^{-1}$ ) respectively as compare to the rest of advance lines, while PR-109 produce minimum grain yield ( $4441\text{kg ha}^{-1}$ ) sown on Oct. 25<sup>th</sup> and Nov. 5<sup>th</sup>. So we recommend that wheat advance lines PR-107 and PR-103 may be preferably sown on Oct 25<sup>th</sup> to Nov. 05<sup>th</sup>, indicating optimum sowing time for producing maximum grain yield in KP zone. Among wheat advance lines on over all planting dates, PR-107, PR-106, PR-103 and PR-105 produced higher average yield especially PR-107 and PR-106 recorded ( $4803\text{kg ha}^{-1}$ ) and ( $4800\text{kg ha}^{-1}$ ) maximum yield. PR-103 and PR-105 were recorded ( $4637\text{kg ha}^{-1}$ ) and ( $4599\text{kg ha}^{-1}$ ) respectively, while PR-109 recorded minimum yield ( $3847\text{kg ha}^{-1}$ ).

## Recommendation

Therefore, wheat advance lines PR-107, PR-106 and PR-103 are recommended in future for normal and late sowing in irrigated areas of KP zone for maximum grain yield. These all lines will be released as new varieties after further testing in regional and national trials.
