Abstract

Human activities contribute to climate change by causing changes in Earth’s atmosphere in the amounts of greenhouse gases, aerosols (small particles), and cloudiness. There may be a vigorous growth of some crops in raised CO₂ conditions, but there is a trade-off because as temperature raises seed production may drop. Droughts and floods linked with rising temperature will likely affect some of the increased growth. Most of the crops till now eliminated and failure has been noticed. Shifting and endangering of the marginal crops is increasing rapidly which a big challenge and threats towards food security. Such changes could result in subsequent crop damage. So, with rising temperature diversity of herbivorous insects and their influence on plants increases generally. Greenhouse gases and aerosols affect climate by altering incoming solar radiation and out-going infrared (thermal) radiation that are part of Earth’s energy balance. Changing the atmospheric abundance or properties of these gases and particles can lead to a warming or cooling of the climate system.

Keywords: Climate Change; Maize; Soybean; yield; GHG; Aerosols

Introduction

A significant change in the Earth’s climate is occurring slowly and gradually and influencing life on the planet earth. Climate can be defined as “expected weather”. When changes in the expected weather occur, we call these climate changes. They can be defined by the differences between average weather conditions at two separate times. Climate may change in different ways, over different time scales and at different geographical scales. In recent times, scientists have become interested in global warming, due to mankind’s impact on the climate system, through the enhancement of the natural greenhouse effect. The Earth is currently getting warmer because people are adding heat-trapping greenhouse gases to the atmosphere. The term “global warming” refers to warmer temperatures, while “climate change” refers to the broader set of changes that go along with warmer temperatures, including changes in weather patterns, the oceans, ice and snow, and ecosystems around the world [1]. Climate refers to the average weather conditions in a place over many years (usually at least 30 years, to account for the range of natural variations from one year to the next). For example, the climate in Swat Pakistan (Especially upper Swat) is cold and snowy in the winter, while Peshawar Pakistan climate is hot and humid.

The climate in one area, like the Swat or Peshawar, is called a regional climate. The regional climates have great importance in respect of agricultural productivity, food security, and livelihood. Recent studies have showed that plants and crop responded positively to regional climate and showed ameliorating effect in term of grain yield, plant height, thousand grain weight, dry matter portioning, biological yield, oil yield, and quality of the crops [2-14]. The average climate around the world is called global climate. When scientists talk about global climate change, they’re talking a pattern of changes happening around the world over many years. One of the most important trends that scientists look at is the average temperature of the Earth, which has been increasing for many years (Figures 1 & 2). Climate is the long-term statistical expression of short-term weather.

Ancient Expansion of Climate Science

The history of the scientific discovery of climate change began in the early 19th century when ice ages and other natural changes in pale climate were first suspected and the natural greenhouse effect first identified. In the late 19th century, scientists first argued that human emissions of greenhouse gases could change the climate. Many other theories of climate change were advanced, involving forces from volcanism to solar variation. In the 1960s, the warming effect of carbon dioxide gas became increasingly convincing. Some scientists also pointed out that human activity that generated atmospheric aerosols...
(e.g., "pollution") could have cooling effects as well. During the 1970s, scientific opinion increasingly favored the warming viewpoint. By the 1990s, as a result of improving fidelity of computer models and observational work confirming the Milankovitch theory of the ice ages, a consensus position formed: greenhouse gases were deeply involved in most climate changes and human caused emissions were bringing discernible global warming. Since the 1990s, scientific research on climate change has included multiple disciplines and has expanded. Research has expanded our understanding of causal relations, links with historic data and ability to model climate change numerically.

Research during this period has been summarized in the Assessment Reports by the Intergovernmental Panel on Climate Change. Climate change is a significant and lasting change in the statistical distribution of weather patterns over periods ranging from decades to millions of years. It may be a change in average weather conditions, or in the distribution of weather around the average conditions (such as more or fewer extreme weather events). Climate change is caused by factors that include oceanic processes (such as oceanic circulation), biotic processes, variations in solar radiation received by Earth, plate tectonics and volcanic eruptions, and human-induced alterations of the natural world. The latter effect is currently causing global warming, and “climate change” is often used to describe human-specific impacts.

Greenhouse Gases Effect and Global Warming

The Sun powers Earth’s climate, radiating energy at very short wavelengths, predominately in the visible or near-visible (e.g., ultraviolet) part of the spectrum. Roughly one-third of the solar energy that reaches the top of Earth’s atmosphere is reflected directly back to space. The remaining two-thirds are absorbed by the surface and, to a lesser extent, by the atmosphere. To balance the absorbed incoming energy, the Earth must, on average, radiate the same amount of energy back to space. Because the Earth is much colder than the Sun, it radiates at much longer wavelengths, primarily in the infrared part of the spectrum. Much of this thermal radiation emitted by the land and ocean is absorbed by the atmosphere, including clouds, and reradiated back to Earth. This is called the greenhouse effect Barnola, Samreen, Anwar, Khan, Imran et al. [3,6,11,12,15].

The glass walls in a greenhouse reduce air flow and increase the temperature of the air inside. Analogously, but through a different physical process, the Earth’s greenhouse effect warms the surface of the planet. Without the natural greenhouse effect, the average temperature at Earth’s surface would be below the freezing point of water. Thus, Earth’s natural greenhouse effect makes life as we know it possible Battle, Imran, Barnola, Imran, Bender et al. [16-19].

It is wisely said that to solve a problem, first you must know and understand the problem. The findings revealed that they have had a hazy picture about the climate change and had many biases on the subject largely due to the news emanating from the local and international knowledge source. Climate change has happened in the past also and is a normal and natural process occurring in a cyclical manner due to changes in the planetary movements. As per the Milankovitch Cycle, there are three planetary movements viz., Obliquity, eccentricity, axial precession, and apsidal precession, which cause a major shift in the climate over a period of 41,000, 100,000, 26,000 and 112,000 years, respectively (see Wikipedia for basic knowledge). But the current climate change is not normal and natural process, rather it is largely anthropogenic in nature Barnola, Imran, Asad, Imran and Asad, Naveed et al. [19-25].

Research over the past one century by scientific communities across the world has indicated that the alarming increase in the amount of different greenhouse gases (GHGs), which include carbon-di-oxide, methane, nitrous oxide, and water vapor in the atmosphere, has buttressed warming of the planet. It has also been discovered that there is a proportional change in the global temperature and GHGs released in the atmosphere and has caused the planet to warm by 1o Celsius in the last one century and is still continuing. Among the GHGs, the share of carbon-di-oxide in global warming is highest due to its higher proportional release. The greenhouse effect caused by such gases, is though important to keep the planet congenial for living, as in the absence of ‘normal warming’ earth will become a cold planet. The excess of anything is detrimental so is the case with GHGs. The CO₂ levels today stand at 402 ppm and is further increasing at an alarming rate. Figure 1 explains how the release of CO₂ by various anthropogenic activities determines its concentration levels in the atmosphere. Figure 3 shows the rate of increment of different GHGs since 0 AD.

![Figure 1: Increasing trends in Mean annual temperature (source, Pakistan Meteorological Department).](image)

Difference between weather and climate, climate change and climate variability

a. Weather: The condition of the atmosphere at a particular place and time. Some familiar characteristics of the weather include wind, temperature, humidity, atmospheric pressure, cloudiness, and precipitation. Weather can change from hour to hour, day to day, and season to season.
b. Climate: The average weather conditions in a particular location or region at a particular time of the year. Climate is usually measured over a period of 30 years or more.

c. Climate change: A significant change in the Earth’s climate. The Earth is currently getting warmer because people are adding heat-trapping greenhouse gases to the atmosphere. The term “global warming” refers to warmer temperatures, while “climate change” refers to the broader set of changes that go along with warmer temperatures, including changes in weather patterns, the oceans, ice and snow, and ecosystems around the world.Battle, Imran, Imran and Asad, Naveed, Imran Khan, Baqa, Iqbal, et al. [5,3,4,6,7,12,38].

d. Climate variability and Global warming: An increase in temperature near the surface of the Earth. Global warming has occurred in the distant past as the result of natural causes. However, the term is most often used to refer to recent and ongoing warming caused by people’s activities. Global warming leads to a bigger set of changes referred to as global climate change.

Weather vs. Climate: It is normal for the weather to change on a daily or even hourly basis. But when the average pattern over many years changes, it is a sign of climate change.

How climate change will affect Agricultural productivity

The global warming caused by climate change is likely to affect crops throughout the growth and development stages due to increased temperature, moisture stress, heat waves, the possible emergence of new major insect-pests and disease etc. (Imran, Imran and Asad, Naveed, Imran Khan, Baqa, Iqbal, Islam, Iqbal et al. [5,3,31-35]) Mungbean has high nutritive value, and due to this, it has advantage over the other pulses known as king of the pulse crop. The seed contains 24.20% protein content, 1.30% fat, and 60.4% carbohydrates; calcium (Ca) is 118 and phosphorus (P) is 340 mg per 100 g of seed. Pulses are known as poor man’s meat and cheap source vegetable protein containing 20–25% protein. Its production is very low in many regions due to lack of management of the inputs. Therefore, if farmers implement more number of tillage practices as compared to conventional, the nutrients demand will be fulfilled by the leached and adsorbed nutrients, away from root zone by pulverizing the soil with more number of, whereas the productivity of the soil will also increase with more soil, promote root density, and will result in more number of nodules having more nitrogen fixation.

Effects on germination

Crop seeds germinate in a particular range of temperature. Increase in soil temperature by global warming will adversely affect germination and therefore crop stand (Khan, Baja, Iqbal, Islam, Iqbal et al, Samreen, Anwar, Khan, Imran et al [1,6,9,11,13,36]) For example, groundnut which is a major crop of Saurashtra has an optimum temperature of 25-30°C for germination. Increase in temperature beyond this range during the sowing time will adversely affect crop germination (Imran, Imran and Asad, Naveed, Imran Khan, Baqa, Iqbal, et al. [3,4,6,7,12,37,38]).

Canola cultivars positively responded to sulphur fertilization in term of seed yield and oil quality. Oscar cultivar increased seed yield 53% as compared to control plots. Sulphur @ 45 kg ha–1 increased seed yield, biological yield, and quality of rapeseed. Number of days to flowering (76), number of pods plant–1 (1372), number of seeds pod–1 (24), plant height (173 cm), biological yield (15547 kg ha–1), seed yield (2209 kg ha–1), index (19%), glucosinolate (μmol g–1) content (31.03 μmol g–1) and oil content (45.81%) was significantly with sulphur treated @ 45 kg ha–1 applied plots as compared to delayed flowering (78 days), shortest (151 cm), pods formation (298 pods), seed pod–1 (21), biological yield (11090 kg ha–1), seed yield (1436 kg ha–1), and oil content (42.62%) in control plots. Among cultivars “Oscar” ranked first in growth stages and attain more plant height (164 cm), and examined substantial number of pods plant–1 (359), seeds pod–1 (24), seed yield (2005 kg ha–1), biological yield (14298 kg ha–1), harvest index 17%, and oil content 46.29% as compared to other sowed cultivars. On the basis of the result it is recommended that cultivar “Oscar” treated with sulphur @ 45 kg ha–1 should be applied for higher yield and quality of rapeseed under agro-climatic condition of Swat valley.

Effects on growth and development

Temperature higher than the optimum range adversely affects growth and development of plants due to harmful effects on plant metabolic activities. The rate of photosynthesis may get more sluggish as the temperature increases due to closure of stomata. Besides, higher temperature enhances the rate of evapo-transpiration causing moisture stress in plants under rain-fed situations. Also at higher temperature the dry matter accumulation becomes less. Shoot cutting duration after date of sowing (ADS), (no cutting, 30 days ADS, 40 days ADS, 50 days ADS and 60 days ADS) were used in the experiment with the test cultivar Dunked. From the results it is observed that rapeseed cultivar positively responded for days to flowering, days to maturity, number of branches plant–1, HI %, number of seeds pod–1, seed weight (g), biological yield (kg ha–1), seed yield (kg ha–1) and oil yield (kg ha–1) to biochar levels maximum seeds pod–1 (23 seeds), thousand seed weight (3.59 g), biological yield (10310 kg ha–1), seed yield 1169 kg ha–1, and oil yield (600 kg ha–1) was observed in plot treated with 10 ton biochar ha–1. Whereas minimum seeds pod–1 (15 seeds), thousand seed weight (2.41 g), biological yield (6725 kg ha–1), seed yield (923 kg ha–1) and oil yield (401 kg ha–1) was recorded in control plot.

Similarly highest seeds pod–1(22), thousand seed weight (3.3 g), seed yield (1099 kg ha–1) was noted in no shoot cutting plot followed by shoot cutting after 60 days of sowing ADS plots while promising biological yield (9025 kg ha–1), and oil yield
(568 kg ha-1) was recorded in shoot cutting after 50 days ADS and after 60 days ADS of sowing. On the basis of the result it was concluded that shoot cutting with 10 ton biochar ha-1 produced highest seed and oil yield with green chop and recommended for higher seed, oil and biological yield in the agro-climatic condition of swat valley.

**Effects on reproduction**

Higher temperature has harmful effects on flowering, pollination, fruit setting, and maturation. Higher temperatures may increase flower and fruit dropping in some crops, and cause stigma and pollens to dry (Imran, Imran and Asad, Naveed, Imran, Khan, et al. [1,5,6,12,24,39]). The anthelmintic activity was very significant against the tested earthworms. Leaf extracts of *Iphiona grantioides* and *Pargvataa* dose of 100 /ml caused death of the worms in 3.33 ±0.57 and 2.16±0.28 minutes, respectively, which is similar to the effect produced by commercial anthelmintic drug, Piperazine Citrate. indicated that both the plants have significant antilice potential by showing 100% lice mortality in case of *Iphiona grantioides* leaf followed by its flower (96.67%) and of *Plucheeargutataby* causing 93.33 % lice mortality. *Iphiona grantioides* showed excellent insecticidal (90%) activity against *Callosobruchusansenii*, *Rhyzoperthadominica*, *Sitophilusoryzae* and *Triboliumcastaneum*. *Plucheeargutataby* exhibited significant activity against all the tested insect species.

The results also depicted excellent effect of both the plants by inhibiting growth of *Lemna minor*. Plant extracts of the plants displayed significant cytotoxicity against brine shrimps. The LD 50 values for all the crude extracts of *Iphiona grantioides* and *Plucheeargutataby* subsp. *glabra* were found to be 34.65, 242.83, 6.21, 29.92 ug/ml and 0.02, 0.03 and 84.66 ug/ml respectively. The present studies showed that ethanolic extracts of *Iphiona grantioides* and *Plucheeargutataby* subsp. *glabra* revealed significant potential regarding anthelmintic, antilice, insecticidal cytotoxic and phytotoxic activity and these plants could be exploited for herbal drugs exploration for the health care of mankind.

**Effects on crop duration**

The increase in temperature will speed the maturity, so cutting the total duration of the crop. It will result in lower dry matter accumulation and lower yield. The effect of nitrogen on days to flowering was significant. With increase in nitrogen level significant delayed were noted in days to flowering. Plots treated with different decapitation stresses delay days to flowering as compared to plots. The interaction between nitrogen levels and decapitation stress on days to flowering were also found significant with 100 kg nitrogen level and 5 cm decapitation stress shows maximum (111) days to flowering. This might be due to maximum nitrogen enhances vegetative growth and delayed reproductive phase. This statement are supported by Ahmadi and Bahrani (2009) who’s reported the effect of nitrogen levels and concluded that highest N level enhanced plant height, number of branches plant-1and maximum days to flowering.

**Effects on crop productivity**

Lower plant stand due to poor germination, low dry matter accumulation, adverse effects on flowering and fruiting, reduced crop duration caused by an increase in temperature will ultimately reduce the crop yield. Still, in case of C3 plants the enhanced level of CO₂ may result in higher rate of photosynthesis and increase yield. But such effects of CO₂ fertilization may get negated due to higher temperature and moisture stress caused by climate change (Imran, Barnola, Imran and Asad, Imran and Asad, et al. [1,5,28,11,40-44]) A study have been reported that regional climate is very important for an ideal crop production and growth. Table 1&2 shows five different crop average yield grown and different elevation and topography with different rainfall pattern and temperature. Difference in the average temperature of a locality have significant effect on crop growth, yield and productivity.

**Relationship Of Carbon and Water Cycle With Climate Change**

**Water and Carbon Cycles**

Cycling of carbon and water are central to supporting life on earth and an understanding of these cycles underpins some of the most difficult international challenges of our times. Both these cycles are included in the core content elements of the specifications for A Level geography to be first taught from 2016. Whether we consider climate change, water security or flood risk hazard an understanding of physical process is central to analysis of the geographical consequences of environmental change. Both cycles are typically understood...
within the framework of a systems approach which is a central concept to much physical geographical enquiry. The concept of a global cycle integrates across scales. Systems theory allows us to conceptualise the main stores and pathways at a global scale. The systems framework also allows for more detailed (process detail) and local knowledge to be nested within the wider conceptual framework. Local studies on aspects of hydrology or carbon cycling can be understood as part of a broader attempt to understand in detail the nature of water and carbon cycling.

Global environmental challenges frequently excite student interest in physical geography but it can be difficult for students to see how they can conduct relevant investigations of fieldwork given the large scale and complexity of the issues. By embedding their knowledge within systems framework students can understand how measurements and understanding derived from their own fieldwork and local studies contribute to the wider project of elucidating the cycling of water and carbon at the global scale. This capacity to link scales means that the study of biogeochemical cycles is intrinsically geographical so that students can understand how processes operate in, and impact upon particular places and how they are distributed in space.

The Water Cycle

Water is present in three phases on earth, as liquid water, as ice and as atmospheric moisture. At the global scale there are stores of water in all three phases. Liquid water dominates with about 98% of water in liquid form; predominantly in the oceans (Table 1) Water is cycled between these stores by a range of key processes as identified in (Figure 2). The mean residence times for various stores vary both with the size of the store (larger stores take longer to turn over) and with the rate of the processes which move water between stores (for example surface runoff is relatively rapid but groundwater flows are much slower so that groundwater residence times can be high).

The Carbon Cycle

Cycling of the element carbon is intimately associated with life on earth. Carbon is present in carbon based molecules that are integral to all living creatures, as carbon dioxide and methane in the atmosphere, in carbonate rocks in the lithosphere and as organic molecules in soils and sediments which are derived from formerly living material. Major carbon stores include the ocean, ocean sediments, soils, bedrock, vegetation and the atmosphere. Atmospheric carbon has become a major policy focus because of the role of carbon dioxide and methane as greenhouse gasses. The magnitude of the major stores and the way in which they are connected by key processes is illustrated in (Figure 3) which is taken from the Intergovernmental Panel on Climate Change (IPCC). This diagram indicates significant anthropogenic perturbations of the carbon cycle since 1750AD. About 90% of anthropogenic carbon release comes from combustion of fossil fuels with the remainder driven by land use change. Of the anthropogenic CO$_2$ released to the atmosphere about 24% is absorbed by the oceans and 26% is taken up by plants. Global CO$_2$ concentrations have increased from less than 320 ppm in 1960 to around 400 ppm at present (see Earth System Research Laboratory website).

Carbon is a ubiquitous element on Earth. Most of the Earth’s carbon is stored in rocks, but this carbon is essentially inert on the 100’s to 1000’s year timescales of interest to humans.

The rest of the carbon is stored as CO$_2$ (carbon dioxide) in the atmosphere (2%), as biomass in land plants and soils (5%), as fossil fuels in a variety of geologic reservoirs (8%) and as a collection of ions in the ocean (85%). These are the “active” reservoirs of carbon of interest in this website. The Earth is warmed by the Sun. This warmth is returned from Earth to the atmosphere in the form of heat radiation. Many gases in the atmosphere, including CO$_2$, absorb the Earth’s heat energy and radiate in all directions. The energy radiated downward warms the surface and lower atmosphere. Adding more CO$_2$ to the atmosphere means more heat radiation is captured by the atmosphere and radiated back to Earth. Methane, CH$_4$, is another very important greenhouse gas that is part of the carbon cycle. This website addresses only CO$_2$. Humans add CO$_2$ to the atmosphere, Nature removes about half of it.
In the 1990’s, humans added $8.0 \times 10^{15}$ grams of carbon ($10^{15}$ grams of carbon = 1 PgC) to the atmosphere each year, primarily by burning fossil fuels (6.4 PgC/yr) and clearing land in the tropics (1.6 PgC/yr). The ocean took up 28% of this carbon, and the land absorbed 32%. Only 40% remained in the atmosphere to cause climate warming. Natural processes are significantly damping the rate of carbon accumulation in the atmosphere. From 2000-2008, humans added 9.1 PgC to the atmosphere each year, 7.7 PgC/yr from fossil fuels and 1.4 PgC/yr from land use change. There is some evidence that a larger fraction of these recent emissions has remained in the atmosphere (45%). Future climate warming depends on both the CO$_2$ source from human emissions and the CO$_2$ sink from natural sinks in the ocean and the terrestrial biosphere.

**Carbon Cycle**

The Basics  Carbon is transferred between CO$_2$ and living or dead organic material by the very basic photosynthesis / respiration reaction (shown here in simplified form).

$$\text{CO}_2 + \text{H}_2\text{O} + \text{energy} \rightleftharpoons \text{CH}_2\text{O} + \text{O}_2$$

When this reaction proceeds to the right, it is the fixation of carbon to organic matter by plants via photosynthesis; and when it proceeds to the left, it is respiration or combustion of that organic matter. Fossil fuels are the remnants of dead organic matter that lived millions of years ago.

**The Global Carbon Cycle**

The carbon cycle is a complex system of biological, chemical and physical processes. A schematic from the IPCC AR4 report is shown here. The schematic shows the major reservoirs of carbon in gigatons of carbon, GtC (1 GtC = 1 PgC: Petagram of Carbon) and the major fluxes in GtC/yr. The numbers shown are the best estimates for the 1990’s.

**Climate change impacting the water cycle?**

Climate change increases our risk of both heavy rains and extreme droughts. But why - and how? Science has shown that climate change touches every corner of our planet’s ecosystem, and the water cycle is no exception. Because the processes involved are highly dependent on temperature, changes in one have consequences on the other. Specifically, as global temperatures have steadily increased at their fastest rates in millions of years, it’s directly affected things like water vapor concentrations, clouds, precipitation patterns, and stream flow patterns, which are all related to the water cycle (Lal, Trembert et al. [45,46] So how does climate change impact the water cycle? We’ve created an info graphic below that illustrates what’s going on, but we’ll describe it here too.

Put simply, water evaporates from the land and sea, which eventually returns to Earth as rain and snow. Climate change intensifies this cycle because as air temperatures increase, more water evaporates into the air: Warmer air can hold more water vapor, which can lead to more intense rainstorms, causing major problems like extreme flooding in coastal communities around the world. But it doesn’t end there. At the same time that some areas are experiencing stronger storms, others are experiencing more dry air and even droughted. Like we mentioned above, as temperatures rise, evaporation increases and soils dry out. Then when rain does come, much of the water runs off the hard ground into rivers and streams, and the soil remains dry.

For each plant variety, there is an optimal temperature for vegetative growth, with growth dropping off as temperatures increase or decrease. Similarly, there is a range of temperatures at which a plant will produce seed. Outside of this range, the plant will not reproduce. As the graphs show, corn will fail to reproduce at temperatures above 95°F and soybean above 102°F (Figures 4 & 5).

**Anthropogenic Activities Leading to Climate Change**

Human activities contribute to climate change by causing changes in Earth’s atmosphere in the amounts of greenhouse gases, aerosols (small particles), and cloudiness. The largest known contribution comes from the burning of fossil fuels, which releases carbon dioxide gas to the atmosphere. Greenhouse gases and aerosols affect climate by altering incoming solar
radiation and out-going infrared (thermal) radiation that are part of Earth’s energy balance lock wood et al. [47]. Changing the atmospheric abundance or properties of these gases and particles can lead to a warming or cooling of the climate system. Since the start of the industrial era about et al. [48], the overall effect of human activities on climate has been a warming influence. The human impact on climate during this era greatly exceeds that due to known changes in natural processes, such as solar changes and volcanic eruptions (Figure 6).

Conclusion

The effect of climate change is not limited to water availability and uneven rainfall distribution only but it also intensifies floods leads to dampen soil, cause storms and also increase the air temperature which increase the risk of drought and affects various agronomic crop yields and thus the food security and worsens the human living environments. Therefore, a well-coordinated program is necessary to create awareness among different sections of the society including the policy makers, general public, organizations, industrialists and farmers.

However, human activities, primarily the burning of fossil fuels and clearing of forests, have greatly intensified the natural greenhouse effect, causing global warming Marengo [49]. The two most abundant gases in the atmosphere, nitrogen (comprising 78% of the dry atmosphere) and oxygen (comprising 21%), exert almost no greenhouse effect. Instead, the greenhouse effect comes from molecules that are more complex and much less common. Water vapor is the most important greenhouse gas, and carbon dioxide (CO₂) is the second-most important one. Methane, nitrous oxide, ozone and several other gases present in the atmosphere in small amounts also contribute to the greenhouse effect. In the humid equatorial regions, where there is so much water vapor in the air that the greenhouse effect is very large, adding a small additional amount of CO₂ or water vapor has only a small direct impact on downward infrared radiation. However, in the cold, dry Polar Regions, the effect of a small increase in CO₂ Shaw et al. [50].
to sustain the food security and the environment in the days to come where climate change has to be experienced around the world.
