Abstract
Twelve Ouda rams aged 2-2.6 years and weighed between 40.21-40.32kg were randomly distributed into 3 groups of 4 animals per group with one ram per replicate in a Completely Randomized Design (CRD) and used to determine the effect of Pergonal® on semen characteristics, hormonal profile and biochemical constituents of the seminal plasma. These groups were assigned to 3 levels of Pergonal® injection as treatments. The levels were 0.00i.u (1.00ml physiological saline), 49.50i.u and 99.00i.u Pergonal® represented as T₁ (control), T₂ and T₃ respectively. All the treatments were administered by intramuscular injections. The injections were divided into three doses each and administered intramuscularly in the thigh for three consecutive days. The results of the study showed that Pergonal® enhanced semen quality and was not detrimental to hormonal profile and biochemical constituents of the seminal plasma of the Ouda rams.

Keywords: Pergonal®; Semen quality; Hormones; Seminal plasma constituents; Ouda rams

Abbreviations: FSH: Follicle Stimulating Hormone; LH: Luteinizing Hormone; ANOVA: Analysis of Variance; CRD: Completely Randomized Design

Introduction
The Ouda sheep is a large long-legged breed with a convex facial profile found in the Sudan Savannah zone especially in the North Western part of Nigeria. It has a characteristic pie-coat colour pattern of an entirely black or brown head and four quarters and white hind quarters. The ears are large, long and droopy. Mature males have horns while females are normally polled (hornless). It has thin tail, the rump is short and extremely sloppy. Mature rams measure 30-60kg, while the females can weigh 30-45kg [1].

The primary aim of induction of spermatogenesis is to improve semen quality [2,3]. Spermatogenesis involves the use of follicle stimulating hormone (FSH) and luteinizing hormone (LH). Most of these preparations of FSH and LH are very expensive perhaps because of the brand names, some of them require cold chain storage and often deteriorate because of inadequate storage and handling [4].

There is therefore the need to examine some generic preparations that could induce spermatogenesis in the animals but at the same time are cheap, readily available and easily managed under developing countries conditions. Pergonal®, a fertility drug also known as Humagon or Mentrophin is a gonadotrophin preparation lyophilized in vials containing a mixture of gonadotrophins consisting of FSH (DFSH) and LH (DLH) in a ratio 1:1 [5]. Follicle stimulating hormone and LH present in Pergonal® play vital role in the initiation of spermatogenesis.

It has not been determined if the administration of the hormone preparation for spermatogenesis and semen production would induce any side effects on the hormonal profile and seminal plasma constituents of the Ouda rams. This study was therefore carried out to determine the effect of Pergonal® administration on semen quality, hormonal profile and Biochemical constituents of the seminal plasma of Ouda rams.

Materials and Methods
Experimental animal and their management
Twelve healthy, sexually matured Ouda rams aged 2-2.6 years were used for this study. The animals were purchased from...
the local markets and housed in clean pens constructed in such a way that the rams could come outside during the day for access to sunlight and forage. The animals were dewormed two times within the experimental period. The actual experimental period lasted for complete 70 days. Routine inspection for cleanliness was carried out. Freshly cut forages consisting of Panicum maximum, Aspilia africana, Pennisetum purpureum (Elephant grass) were fed as basal diet and a concentrate ration of Grower Mash was used as supplement. The animals were fed twice daily (in the morning and evening). Salt lick was provided as mineral supplement. Water was given ad libitum to the animals.

Experiment design and drug administration

The twelve Ouda rams were divided into 3 experimental groups consisting of 4 animals per group with one ram per replicate in a Completely Randomized Design (CRD). These groups were assigned to 3 levels of Pergonal® as treatments. The levels of Pergonal® were 0.00i.u, 49.50i.u and 99.00i.u represented as T1, T2, and T3 respectively. T0, which contained no Pergonal® served as the control. The rams were treated by intramuscular injections.

The injections were given as follows:

Pergonal was supplied in 5 vials, each vial containing FSH 75i.u and LH 75i.u. The content of the first vial was dissolved in 1ml of physiological saline solution immediately prior to use, resulting in a solution of PFSH 75i.u plus PLH 75i.u per ml.

All treatments were administered intramuscularly on the hind leg (thigh) of each ram using a one ml syringe with 0.01ml graduation.

Semen collection and evaluation

Semen collection was done by electro-ejaculation method [6] after one week of Pergonal® administration and continued at 2 weeks interval for 9 weeks. The semen was collected between 8:00am and 9:00am. This was to ensure that quality semen would be obtained. A transparent graduated tube immersed in a protective jacket containing water at 37 °C, with a funnel was used to collect the semen. The animal’s hind limbs were held up by an assistant, with shoulder and fore limbs of the animal held tightly between the two legs of the assistant. The Vaseline lubricated probe was inserted gently into the rectum. The rhythmic stimulation of the ampullae and sacral nerve plexus caused erection and subsequently ejaculation within few minutes.

Semen evaluation was done as promptly as possible post collection as described by [7] for qualitative and quantitative parameters such as semen volume, semen pH, sperm concentration, sperm motility, live sperm percentage, dead sperm percentage.

Hormonal assay

Blood sample (5ml each) were obtained with needle and syringe by jugular vein puncture of the twelve rams on day 7 after the Pergonal® injection for testosterone, FSH and LH evaluation. It was cooled immediately in iced water and transferred to the laboratory, refrigerated at 4 °C for 1 hour and the serum separated by centrifugation at 5,000rpm for 10 minutes. The serum was stored immediately at -20 °C until enzyme immune assayed (EIA) for testosterone, FSH and LH as described by [8].

Biochemical constituents of seminal plasma

Semen samples used for estimation of biochemical constituents of seminal plasma were centrifuged at 15,000rpm for 15 minutes. The seminal plasma samples were immediately subjected to laboratory analysis for the following biochemical parameters: urea, glycerophosphocholine, ascorbic acid, sodium, potassium, bicarbonate and fructose (Table 1 & 2).

Sodium and potassium concentrations were estimated with a flame photometer on samples suitably diluted with deionized water, while bicarbonate and urea concentrations were determined according to the method of [9]. Fructose concentration in the plasma was determined according to the procedure of [10]. Glycerophosphocholine and ascorbic acid concentrations were determined according to the method [11].

Data analysis

Data collected on semen characteristics, hormonal profile and seminal plasma constituents of Ouda rams were subjected to analysis of Variance (ANOVA) using the technique of [12]. Significant treatment means were separated using Duncan’s New Multiple Range Test as described by [13].

Results and Discussion

The results of Pergonal® administration on semen characteristics of Ouda rams are shown in (Table 3). There were significant difference (P<0.05) among the treatment groups in semen volume. Rams on T3 recorded the highest value of 1.12ml in semen volume and this was significantly different (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T1 in semen volume. There was no significant difference (P>0.05) between rams on T2, and T3 in semen volume. The highest

---

There were significant differences (P<0.05) among the treatment groups in mass motility. Rams on T2 and T3 recorded the highest value of 4.55 in mass motility and this differed significantly (P<0.05) from rams on T1 which were similar (P>0.05) to rams on T2 in percentage of live sperm cells. There was no significant difference (P>0.05) between rams on T1 and T2 in percentage of live sperm cells. The percentages of live sperm cells obtained in this study were lower than the range of 77.2+9.7-79.4+ 4.9% reported in Nigerian Yankasa rams, except rams on T3 whose percentage live sperm cells was within the range.

There were significant differences (P<0.05) among the treatment groups in individual motility. The lowest score in individual motility obtained in this study (80.20%) was lower than the score of 85.0+7.5% reported by in Yankasa rams of similar ages [15]. There were no significant differences (P>0.05) among the treatment groups in percentage of live sperm cells. Rams on T3 recorded the highest percentage of live sperm cells (86.00%) and this differed significantly (P<0.05) from rams on T1 which were similar (P>0.05) to rams on T2 in percentage of live sperm cells. There was no significant difference (P>0.05) between rams on T1 and T2 in percentage of live sperm cells. The percentages of live sperm cells obtained in this study were lower than the range of 77.2+9.7-79.4+ 4.9% reported in Nigerian Yankasa rams.

There were significant differences (P<0.05) among the treatment groups in percentage of normal sperm cells. Rams on T3 recorded the highest percentage of normal sperm cells (90.00%) and this differed significantly (P<0.05) from rams on T1 which were similar (P>0.05) to rams on T2 in percentage of normal sperm cells. There was no significant difference (P>0.05) between rams on T1 and T2 in percentage of normal sperm cells. The percentages of normal sperm cells obtained in this study were within the range of 82.4+3.8- 87.0+8.2% reported in Nigerian Yankasa rams.

There were significant differences (P<0.05) among the treatment groups in percentage of dead sperm cells. Rams on T1, T2 and T3 recorded the highest value of 85.0+7.5% in percentage of dead sperm cells. There was no significant difference (P>0.05) between rams on T2 and T3 in percentage of dead sperm cells. The lowest score in percentage of dead sperm cells was observed in rams on T1. The highest score in individual motility obtained in this study (80.20%) was lower than the score of 85.0+7.5% reported by in Yankasa rams of similar ages. Sperm motility is affected by frequency of semen collection.

There were no significant differences (P>0.05) among the treatment groups in semen pH. Rams on T2 and T3 recorded the highest numerical value of 8.00 in semen pH. The lowest numerical value in semen pH was observed in rams on T1 (7.80). Semen pH values obtained in this study were within the normal range of 7-8 reported by [17]. The measured pH depends on the length of time since ejaculation and it tends to increase shortly after ejaculation as a result of loss of CO₂.

There were significant differences (P<0.05) among the treatment groups in sperm concentration. Rams on T3 recorded the highest value of 0.85 (×10⁶/ml) in sperm concentration and this differed significantly (P<0.05) from rams on T1 which were similar (P>0.05) to rams on T2. There was no significant difference (P>0.05) between rams on T1 and T2 in sperm concentration. The highest sperm concentration value of 0.85 (×10⁶/ml) obtained in this study was within the highest value of 0.79+0.07 (×10⁶/ml) for sperm concentration reported by in Yankasa rams of similar ages. This was also within the normal range of 200 to more than 1,000 million sperm/ml reported by [18]. Normally an increase in the semen collection frequency is associated with a decrease in sperm concentration [19,20].

The result of Pergonal administration on hormonal profile of Ouda rams are shown in (Table 4). There were significant differences (P<0.05) among the treatment groups in follicle stimulating hormone (FSH). Rams on T3 recorded the highest value of 11.80 i.u/L in FSH and this differed significantly (P<0.05) from rams on T1 which were similar (P>0.05) to rams on T2.

The observation in this study that the group that received the highest (0.66ml) dose of the test drug recorded the highest percentage of live sperm cell, normal sperm cells and lowest percentage of dead sperm cells suggest that a high dose of the drug such as 0.66ml/ram within 3 days given in this study could have high capacity for induction of spermatogenesis, improvement of semen quality and have no deleterious effects on sperm cells.

The mean ejaculate volume of 1.25+0.7ml reported by [14] in Yankasa rams of similar ages [15] noted that methods of semen collection, season of the year, breed, age, body weight of animal, scrotal circumference and frequency of semen harvest can affect ejaculate volume in rams.

### Table 3: Effect of Pergonal® on Semen Characteristics of Mature Ouda Rams.

Means within row having different superscript are significantly (P<0.05) different. SEM=Standard error of means.

on T1 in FSH values. There was no significant difference (P>0.05) between rams on T2 and T3 in FSH values. The lowest value in FSH was observed in rams on T2 (10.75iu/L). The observation in this study that the FSH value in the rams treated with 0.33ml Pergonal was higher than in the group that received higher dose of the drug suggest that a high dose of the drug such as 0.66ml/ram with 3 days given in this study could excite suppressive effect on the hypothalamus.

Table 4: Effect of Pergonal® on Hormonal Profile of Mature Ouda Rams. Means within row having different superscript are significantly (P<0.05) different. SEM=Standard error of means.

</tbody>
</table>

There were significant differences (P<0.05) among the treatment groups in luteinizing hormone (LH). Rams on T2 recorded the highest value of 5.86(iu/L) in LH and this differed significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in LH values. There was no significant difference (P>0.05) between rams on T1 and T3 in LH values. The lowest value in LH was observed in rams on T1 (5.40(iu/L)). The observation in this study that the LH value in rams on the control treatment (T1) was higher (P<0.05) than in the group that received higher dose of Pergonal® suggest that the higher dose of the drug given in this study 0.66ml/ram within 3 days could excite suppressive effect on the hypothalamus. It is common knowledge that LH as interstitial cell stimulating hormone (ICSH) stimulates the interstitial cells of the testis to produce testosterone which facilitates the process of spermatogenesis.

There were significant differences (P<0.05) among the treatment groups in serum testosterone. Rams on T2 recorded the highest value of 18.50ng/ml in testosterone and this differed significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in testosterone values. There was no significant difference (P>0.05) between rams on T2 and T1 in testosterone values. The testosterone values obtained in this study were within the normal range of 0-20ng/ml reported in Sheep [21].

The results of Pergonal administration on biochemical constituents of the seminal plasma of Ouda rams are shown in (Table 5). There were significant differences (P<0.05) among the treatment groups in seminal plasma urea. Rams on T2 recorded the highest value of 44.80(mg/100ml) in seminal plasma urea and this differed significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in urea level in seminal plasma. There was no significant rams on T1 and T3 in urea level in the seminal plasma. The values for urea in seminal plasma obtained in the Pergonal treated group were lower than the normal range of 17-42mg/dl reported by [23,24] reported that sharp increase in plasma urea level could result in gonadal degeneration and infertility with reduced sperm production and loss of libido.

Table 5: Effect of Pergonal® on Biochemical Constituents of Seminal Plasma of Mature Ouda Rams. Means within row having different superscript are significantly (P<0.05) different. SEM=Standard error of means.

There were significant differences (P<0.05) among the treatment groups in ascorbic acid level. Rams on T2 recorded the highest value of 7.60(mg/100ml) in ascorbic acid in the seminal plasma and this differed significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in ascorbic acid level in the seminal plasma. There was no significant difference (P>0.05) between rams on T1 and T3 in Ascorbic acid level in the seminal plasma. The lowest value in Ascorbic acid was observed in rams on T3 (5.70mg/100ml). Studies have shown that vitamin C plays a vital role in enhancing sperm motility, keeping sperm strong by protecting them from free radicals [25].

There were significant differences (P<0.05) among the treatment groups in citric acid level in the seminal plasma. Rams on T2 recorded the highest value of 137(mg/100ml) and this different significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in citric acid level in the seminal plasma. There was no significant difference (P>0.05) between rams on T1 and T3 in citric acid levels in the seminal plasma. The lowest level of citric acid in the seminal plasma was observed in rams on T1 (123.00mg/100ml). Citric acid and Ascorbic acid are known to have very similar properties [26].

There were no significant differences (P>0.05) among the treatment groups in seminal plasma sodium. Rams on T2 recorded the highest numerical value of 46.80(mmol/L) in seminal plasma sodium. The lowest numerical value in seminal plasma sodium was observed in rams on T1 (45.60(mmol/L). Sodium bicarbonate in seminal plasma stimulates sperm motility [27].

There were significant differences (P<0.05) among the treatment groups in seminal plasma potassium. Rams on T2 recorded the highest value of 5.90(mmol/L) in seminal plasma potassium and this differed significantly (P<0.05) from rams on T1, which were similar (P>0.05) to rams on T3 in potassium values. There was no significant difference (P>0.05) between rams on T2 and T3 in seminal plasma potassium values. Potassium is known to maintain sodium levels and facilitate blood circulation and flow [28].
There were significant differences (P<0.05) among the treatment groups in seminal plasma bicarbonate. Rams on T3 recorded the highest value of 255.00(mmol/L) in seminal plasma bicarbonate in this study were higher than the mean value of 20.00(mmol/L) reported who also inferred that sodium bicarbonate in seminal plasma stimulates sperm motility.

There were significant differences (P<0.05) among the treatment groups in seminal plasma fructose. Rams on T1 recorded the highest value of 255.00(mmol/L) in seminal plasma fructose and this differed significantly (P<0.05) between rams on T2 which were similar (P>0.05) to rams on T3 in bicarbonate values. There was no significant difference (P>0.05) between rams on T3 and T1 in bicarbonate values. The bicarbonate values obtained in this study were higher than the mean value of 20.00(mmol/L) reported who also inferred that sodium bicarbonate in seminal plasma stimulates sperm motility.

**Conclusion**

The results of this study showed that Pergonal® improved semen quality and biochemical constituents of seminal plasma at the level of 99.00iu without any deleterious effects on hormonal profile. Although the hormonal levels fall within the normal ranges for adult sheep, the variations observed suggest the need to constantly monitor hormonal profile of Ouda rams under Pergonal® treatment.
