Abstract

Background: Acne vulgaris is not only the most common endocrinology and skin disorder, but it causes considerable QoL worsening. The social, psychological, and emotional impairment of the disease, can be associated with those caused by epilepsy, asthma, diabetes, and other socially important chronic diseases.

Objective: This study aims to determine the impact of acne on quality of life in Bulgaria using the Cardiff acne disability index (CADI).

Methods: A pilot cross-sectional survey was conducted in a sample of individuals aged 11 to 30 (n=30) from Sofia, Bulgaria that were diagnosed with acne. Cardiff Acne Disability Index (CADI) was applied to collect the data. The CADI scale was translated into Bulgarian and standardized by forward translation, backward translation, and a pretest. The data collected were proceeded through SPSS ver. 22.0.

Results: Mean participant age was 21.7 year. Severe acne was more common among females than males (20% vs. 13.3%). There is no significant prevalence of the disease with the age (p=0.125). BMI is not a factor. The maximum CADI score for the sample was 11 in the male group. The mean score was 6.1±1.12 which implied that the majority of them had moderate impairment and mild psychological impact.

Conclusion: Cardiff Acne Disability Index is a good tool to be assessed the quality of life in patients with acne. The result from the pilot study shows that acne worsens the QoL of the patients affected. The situation of the Bulgarian patients with acne is the same as in the rest of the Eastern Europeans from QoL point of view. Because the venue of this study is pharmacy and not a hospital, it may help patients with low socioeconomic status to consult and ask for appropriate treatment.

Introduction

Acne vulgaris is a common inflammatory pilosebaceous disease with prevalence reaching up to 80% during adolescence, characterized by comedones, papules, pustules, inflamed nodules, etc. [1,2]. Acne is not only the most common endocrinology and skin disorder, but it is also the pathology with the highest cumulative incidence among the general population [3].

It is estimated to affect 9.4% of the global population, making it the eighth widespread disease worldwide [4,5]. According to some studies it affects over 80% of teenagers (aged 13–18 years) at some point [6]. The data about the disease’s prevalence vary depending on the study populations and the method of assessment applied. Prevalence of acne in a community sample of 14- to 16-year-olds in the UK has been recorded as 50% [7]. Overall incidence is similar in both men and women, and peaks at 17 years of age [8]. The data about New Zealand, shows that acne was present in 91% of males and 79% of females, in a similar population in Portugal the prevalence was 82% [9,10].

It has been estimated that up to 30% of teenagers have acne of sufficient severity to require medical treatment [8]. The number of adults with acne, including people over 25 years, is increasing; the reasons for this increase are uncertain [11]. Some authors confirm that the cumulative incidence of acne is 91% in males and 79% in females during adolescence, that drops to 3% in males and 12% in females during adulthood [12]. Different studies reported an acne incidence of 55% in males and 45% in females aged 14 to 16 years [7], whilst other authors stated a 29% incidence in boys and 16% in girls, per year, in a population aged between 16 and 20 years old [13]. White et al. reported an acne incidence of 85% in male adolescents and 80% in female adolescents, which dropped to 8% in the age group 25 to 34 and 3% in those aged 35 to 44 years [14].

The prevalence of acne varies by gender and age groups, appearing earlier in females (11 years old) than in males (12-13 years old), and the reason for that can be the earlier onset of...
Acne vulgaris is a chronic inflammatory disease with a complex pathogenesis that affects predominantly adolescents. Use in teenagers and young adults with acne. It is self-explanatory and can be simply handed to the patient who is asked to complete it without the need for detailed explanation. Each question contains 4 possible answers with a score of 0–4. The CADI score is calculated by summing the score of each question resulting in a possible maximum score of 15 and a minimum score of 0. A score of 0–5 translates to mild quality of life impairment, 6–10 indicates moderate impairment, and 11–15 demonstrates severe impairment. The CADI scale was translated into Bulgarian and standardized by forward translation, backward translation, and a pretest [32]. The data collected were proceeded through SPSS ver. 22.0.

Results

A total of 40 patients were included in the pilot study – 20 males and 20 females. The number of completed questionnaires returned was 30, a response rate of 75% while 10 (25%) questionnaires were incomplete. Mean participant age was 21.7 year. Severe acne was more common among females than males (20% vs. 13.3%). There is no significant prevalence of the disease with the age (p=0.125). BMI is not a factor. The mean BMI is 23.8±4.8 (Table 1).

The results from the CADI.

The maximum CADI score of 15 was not achieved. The maximum CADI score for the sample was 11 in the male group. The mean score was 6.1±1.12 which implied that the majority of them had moderate impairment and mild psychological impact. There was no significant association between CADI score and gender (p=0.123) (Table 2). It is an important finding, as there is a perception among some health professionals that facial acne has less impact on males.

Discussion

Acne vulgaris is a chronic inflammatory disease with a complex pathogenesis that affects predominantly adolescents.

Materials and Methods

A pilot cross-sectional survey was conducted in a sample of individuals aged 11 to 30 (n=30) from Sofia, Bulgaria that were diagnosed with acne. Patients were recruited from pharmacies in Sofia, based on referrals from pharmacists. The Ethics Committee of the Medical University of Sofia approved the study protocol. All participants provided written informed consent before entering the study, and all questionnaires were made anonymous before evaluation.

Data were collected via the Cardiff Acne Disability Index (CADI). The Cardiff Acne Disability Index (CADI) Modley & Finlay [31] is a short 5 item questionnaire derived from the longer Acne Disability Index. The Cardiff Acne Disability Index is designed for

Disability Index. The Cardiff Acne Disability Index is designed for...
It affects quality of life. Our study shows that males were more affected than females in the age group 18–21. The QOL is more affected negatively in the age group 21–25 years, and this result agrees with some conclusions in the literature [33]. In the current study, the males’ QOL was significantly more affected than that of females, from severity point of view as agrees with other studies [34], and this may be because the females take more care about their hygiene and appearance in the community. The results from our study shows nearly the same results as the similar study in Greece [35]. Of course the results cannot be directly compared as different questionnaires were applied.

But as quality of life is completely a subjective issue, the severity of lesions cannot exactly determine the quality of life. There are some other factors that must be considered, such as social, personal, emotional, and school problems [36]. In the present study, there was no significant relationship between quality of life and duration of diseases. This result emphasizes the point that the effect of acne on quality of life is independent of disease duration and is mostly dependent on personal characteristics and patients’ ability in accepting their disease and coping with its problems. These results confirm the results from Kokandi study [37]. The study results confirm the seriousness of the disease and shows that it influences on patients’ quality of life is comparable to some social and rare diseases such as liver, kidney diseases and diabetes [38-40].

**Conclusion**

Cardiff Acne Disability Index helps to assess the quality of life in patients with acne. The CADI contains five questions that focus on feelings, social life, avoidance of public activities and assessment of acne severity (maximum possible score 15). The result from the pilot study shows that acne worsens the QoL of the patients affected. The situation of the Bulgarian patients with acne is the same as in the rest of the Eastern Europeans from QoL point of view.

Because the venue of this study is pharmacy and not a hospital, it may help patients with low socioeconomic status to consult and ask for appropriate treatment. Despite this limitation, this is the first study to be achieved regarding QOL of patients with acne and it can be used as a base for future studies about QOL of patients with skin diseases.
