Abstract
Heterotopic pregnancy is defined as the coexistence of intrauterine and extrauterine gestation. The incidence of heterotopic pregnancy is very low. The frequency was originally estimated on theoretical basis to be 1 in 30,000 pregnancies. We present a rare case of heterotopic pregnancy with non viable intrauterine gestation and right adnexal gestation in a natural conception.

Keywords: Transvaginal sonography; Heterotopic pregnancy; Intra-uterine contraceptive device

Case Presentation
A 32-year-old woman with 6 weeks of amenorrhea presented for emergency ultrasound scan of pelvis with clinical features of p.v. bleeding, lower abdominal pain. Urine pregnancy test was positive.

Transvaginal ultrasound revealed mild amount of free fluid in the peritoneal cavity with an intrauterine gestation corresponding to 4 weeks 4 days. Subchorionic hematoma is noted. A complex ill defined right adnexal mass measuring approximately 4.6x3.4cm was also noted (Figure 1). The Doppler study of right adnexal mass showed low resistance flow.

Pathology confirms the diagnosis of right tubal ectopic pregnancy and non viable intrauterine gestation.

Discussion
A heterotopic gestation is difficult to diagnose clinically. Typically, laparotomy is performed because of tubal pregnancy. At the same time, uterus is congested, softened, and enlarged; ultrasound examination can nearly always show gestational products in uterus.
The incidence was originally estimated on theoretical basis to be 1 in 30,000 pregnancies. However, more recent data indicate that the rate is higher due to assisted reproduction and is approximately 1 in 7000 overall and as high as 1 in 900 with ovulation induction [1].

The increased incidence of multiple pregnancy with ovulation induction and IVF increases the risk of both ectopic and heterotopic gestation. The hydrostatic forces generated during embryo transfer may also contribute to the increased risk [2] (Figure 3 & 4).

Figure 3: Left ovary shows corpus luteal cyst.

Figure 4: Iucd Seen In Cervix.

There may be an increased risk in patients with previous tubal surgeries [3].

Heterotopic pregnancy can have various presentations. It should be considered more likely

a. After assisted reproduction techniques.

b. With persistent or rising chorionic gonadotropin levels after dilatation and curettage for an induced/spontaneous abortion.

c. When the uterine fundus is larger than for menstrual dates.

d. When more than one corpus luteum is present in a natural conception.

e. When vaginal bleeding is absent in the presence of signs and symptoms of ectopic gestation [4].

A heterotopic gestation can also present as hematometra and lower quadrant pain in early pregnancy [5].

Most commonly, the location of ectopic gestation in a heterotopic pregnancy is the fallopian tube. However, cervical and ovarian heterotopic pregnancies have also been reported [6,7].

Majority of the reported heterotopic pregnancies are of singleton intrauterine pregnancies. Triplet and quadruplet heterotopic pregnancies have also been reported, though extremely rare [8,9]. It can be multiple as well [4]. They can be seen frequently with assisted conceptions.

Intrauterine gestation with hemorrhagic corpus luteum can simulate heterotopic/ectopic gestation both clinically and on ultrasound. Other surgical conditions of acute abdomen can also simulate heterotopic gestation clinically and hence the difficulty in clinical diagnosis. Bicornuate uterus with gestation in both cavities may also simulate a heterotopic pregnancy.

High resolution transvaginal ultrasound with color Doppler will be helpful as the trophoblastic tissue in the adnexa in a case of heterotopic pregnancy shows increased flow with significantly reduced resistance index.

The treatment of a heterotopic pregnancy is laparoscopy/ laparotomy for the tubal pregnancy

The illustrated case did not have any risk factor for the heterotopic gestation and presented with ruptured tubal pregnancy and history of p.v.bleeding. Patient did not suspected pregnancy as she had IUCD insertion and was post partum last delivery 8 months back.

A heterotopic pregnancy, though extremely rare, can still result from a natural conception; it requires a high index of suspicious for early and timely diagnosis; a timely intervention can result in a successful outcome of the intrauterine fetus.

Conclusion

A spontaneous heterotopic pregnancy can occur in patients who have no known predisposing factor. Early diagnosis has made this disorder amenable to appropriate management. The high-resolution Transvaginal Sonography is very helpful in the diagnosis of this condition [10,11].
Acknowledgement

The author would like to thank the pathologists, gynaecologists who provided very important feedback with regard to the clinical aspect of this patient’s condition. They contributed significantly to the patient being promptly diagnosed and receiving a high standard of care.
