Abstract

In low and middle income countries, burns are a major global public health problem. The burden of injury primarily affects low socioeconomic population [1]. Children are mainly affected by this problem (usually less than 5 years old) [3,4]. Basic measures applied to these patients may increase better outcomes even in health care centers that lack specialized resources. The initial assessment of a burn patient is different from any patient exposed to trauma. Basic concepts should be applied and followed on this type of patients. The so called ABCDE is a short and easy to apply mnemonic in all of them. Pre-Burn center care is of paramount importance, and simple measures such as wound irrigation with cold water may be of great benefit for patients that are in need for a long distance transfer. This and an early fluid resuscitation greatly enhance the process of initial care in any burn patient. In the setting of a patient being treated in a rural or primary health care center, a proper initial evaluation and treatment as well as an early transfer to a specialized burn center is of paramount importance.

Introduction

In low and middle income countries, burns are a major global public health problem [1]. The burden of injury primarily affects low socioeconomic population [2]. Children are mainly affected by this problem (usually less than 5 years old) [3,4]. Basic measures applied to these patients may increase better outcomes even in health care centers that lack specialized equipment, plastic surgeons or facilities to take care of burn patients. This review is aimed to highlight the most important aspects of the management of patients with second and third-degree burns in a rural or primary health care center prior to its transfer to a proper specialized burn facility.

Patients suffering burn injuries are prone to develop a wide range of complications depending on the affected total body surface area affected. Patients with more than 20% of total body surface area may be prone to develop severe complications such as renal failure, infections and death. Not to mention the irreversible cosmetic complications.

Most burn resuscitation formulas estimate fluid requirements using the burn size as a percentage of TBSA (%TBSA). The “rule of nines” is a quick and effective method of estimating burn size. In adults, the anterior and posterior trunk each account for 18%, each lower extremity is 18%, each upper extremity is 9%, and the head is 9%. Palms and genitalia account for 1% [5]. In children under 3 years old, the head accounts for a larger surface area. Only second and third-degree burns should be included when calculating the %TBSA.

Discussion

Initial management

The initial assessment of a burn patient is no different of any patient exposed to trauma. Basic concepts should be applied and followed on this type of patients. The so called ABCDE is a short and easy to apply mnemonic in all of them.

A is for airway: A patent airway with cervical protection is the mainstay of the initial assessment. Signs of airway injury should be always suspected in patients exposed to burns in a closed environment. If intubation is required there should be no delay for it since airway edema may develop, making intubation difficult or impossible.

B is for breathing: Difficulties on breathing should alert the physician for circumferential burns in chest or abdomen as well
as associated injuries such as thoracic trauma that may require additional invasive procedures.

**C is for circulation:** Insertion of one or two large bore peripheral IV catheters for fluid resuscitation is the mainstay in this part of the evaluation. Burn patients do not usually bleed. So if bleeding is found, an associated cause should be identified. Adequate monitoring of the circulatory status is mandatory.

**D is for neurological deficit:** Basic neurological evaluation with the GCS is a very easy and practical way to rapidly assess for any neurological deficit and even the need to intubate a burn patient when GCS is less than 8.

**E is for exposure:** Burn patients should have all their clothes and accessories such as bracelets or necklaces removed when arriving at the medical center, especially on a history of a chemical burn (since delay of this basic maneuver may worsen injuries). Anterior and posterior evaluation of the whole body should be assessed for injuries. After the evaluation, dry and clean sheets or towels should cover the patient to avoid hypothermia.

Patients with a burned body surface area of 20% are prone to develop gastric distention, nausea or vomiting so they must have a nasogastric tube placed as well as a Foley catheter for fluid balance [6].

**Fluid resuscitation**

Pre-Burn center care is of paramount importance. An early fluid resuscitation greatly enhance the process of initial care in any burn patient [7]. Those with burns of less than 10% of total body surface area may receive an oral resuscitation (unless the digestive tract or airway are affected by concomitant trauma). Burns greater than 10% total body surface area requires at least one peripheral intravenous line (or intraosseous line in children) for fluid resuscitation. Patients with a 30% affected body surface area may need two large bore peripheral IV catheters.6 The parkland formula (Table 1) is a practical way to determine the amount of fluid needed for an adequate resuscitation [6,8]. Half of the total volume obtained by the Parkland formula is administered on the first 8 hours after the initial insult and the remaining is given on the next 16 hours.

**Table 1:** Parkland formula (ABLS 2014)77.

<td>Thermal and chemical burns (Adults)</td>
<td>2 ml x %Burned BSA x Weight</td>
</tr>
<tr>
<td>Pediatric patients (14-yo and Body weight of less than 40kg)</td>
<td>3 ml x %Burned BSA x Weight</td>
</tr>
<tr>
<td>High voltage electric injuries (evidence of deep tissue injury or hemoglobinuria)</td>
<td>4 ml x %Burned BSA x Weight</td>
</tr>
</tbody>
</table>

**Pain control**

NSAIDs may play an important role in those patients that have a low risk of renal failure (non-diabetic, elderly or both, among others). Opioids may be safely indicated in patients with severe pain [9]. Subcutaneous and intramuscular administration should be avoided [6].

**Wound management**

From partial thickness to full thickness burns, simple coverage is necessary. Clean and dry sheets or towels may function as an effective coverage of wounds in burned patients since they provide a dry and warm environment avoiding heat loss. Some evidence suggests that an early and aggressive approach towards full thickness burns may be of great benefit (short and long term) in patients whom are treated in a burn center but not to those treated in a rural or primary health care center [10,11].

Irrigation with cold water is considered an adequate first-aid treatment for burn injuries [12]. Superficial burns do not require antibiotics or special occlusive dressings. Nevertheless, deeper burns require topical antimicrobials or an absorptive occlusive dressing. Silver-based dressings or ointment such as sulfadiazine should be used if available [13]. Tetanus immunization is advised for any patient suffering a burn injury [6].

**Guidelines for referral to a burn center**

**Table 2:** Guidelines for referral to a burn center.

<thead>
<tr>
<th>Partial-thickness burns greater than 10% TBSA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Burns involving the face, hands, feet, genitalia, perineum, or major joints</td>
</tr>
<tr>
<td>Third-degree burns in any age group</td>
</tr>
<tr>
<td>Electrical burns</td>
</tr>
<tr>
<td>Chemical burns</td>
</tr>
<tr>
<td>Inhalation injury</td>
</tr>
<tr>
<td>Burn in a patient with complicated pre-existing medical problem</td>
</tr>
<tr>
<td>Burned children in hospitals without qualified pediatrician</td>
</tr>
<tr>
<td>Burn injury in patients who will require special social, emotional, or rehabilitative intervention</td>
</tr>
</tbody>
</table>

**Conclusion**

Each burn patient requires individualized care. Therefore, in the setting of a patient being treated in a rural or primary health care center a proper initial evaluation and treatment as well as an early transfer to a specialized burn center is of paramount importance.
