## Abstract

Nanotechnology is no more new to the chemical world however everyday development in this field has made it the buzz word of the decade. Its all-embracing impact on more than one discipline has turned it to be a shining star in the eyes of chemists. One of the most noteworthy application of nanotechnology is in field of catalysis. Nanocatalysts have emerged out with substantial characteristics concerning selectivity, activity, lifetime and recoverability. Nanocatalysts are found to be much more effectual and profitable as large part of catalytic atoms is available to the reactants thereby increasing its efficiency manifold as compared to conventional catalysts. The present article is just an overview encompassing the introduction of nanocatalysts with dimensions affecting their catalytic performance (Figure 1).

## Introduction

Nanoscience is one of the most influential technology area of the 21<sup>st</sup> century. Due to the inimitable properties of nanoengineered materials, they are seen to have a giant potential in several areas, such as food packaging, pathogen detection, targeted drug delivery, blood purification, production of antibacterial textiles etc. Nanotechnology has aroused as a burgeoning area taking on loftier significance all over the world. The precise manipulation and control of matter

at dimensions of (1-100) nanometers have revolutionized many industries making it a subject of growing interest [1].

Enormous varieties of nanoparticles have emerged in our everyday life, in field from drugs and electronics to paints and beauty care. One of the most imperative application of nanoparticles is related with catalysis. The nanoparticles of numerous materials display amazing properties, allowing them to be used as the catalysts [2]. Currently, application of

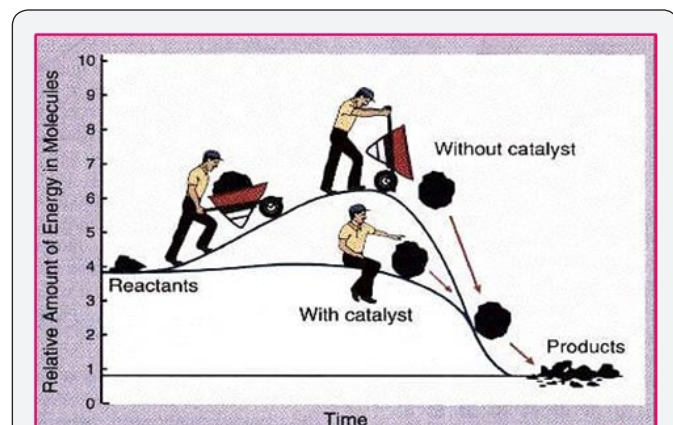

the catalysts in the form of nanoparticles or their colloidal solutions is at the pivotal point as a result good proportion of newfangled possibilities has been unwrapped in the field of chemical synthesis [3].

In terms of chemistry, catalyst is defined as a substance that causes or accelerates a chemical reaction without itself being affected and this process is known as catalysis. A catalyst can make a reaction go faster and in more selective manner. It means that the catalyst enters the reaction and makes some changes in chemical reaction but remains without changes. Even though the catalyst has lower weight than the raw materials, it is the heart of reaction and an appropriate selection of the catalyst for a reaction is very important. Nanoparticles have accomplished many challenges as catalysts by having active sites with a core of metal atoms, metal ions and making holes around the sites. It is predicted that the next generation of catalysts are nanocatalysts which are involved in many of the chemical processes. The present article exemplifies the new generation of catalyst, named nanocatalyst.

### Elementary Features of Catalysts

The most basic characteristics for a catalyst are:

a) The catalyst just augments the reaction (Figure 2) while it remains as such without any changes.

**Figure 2:** Diagram representing catalyst lowering the activation energy thereby accelerating the reaction.

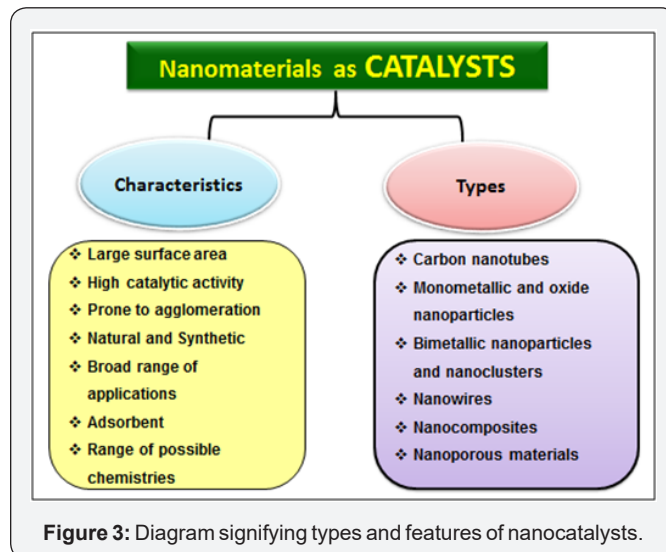

b) A reaction can be carried out by different mechanism but the catalyst should be highly selective thereby escalating the production level of desirable material.

c) In a reversible reaction, the catalyst effects on both reactions. So the system equilibrium percentage should remain unaltered with or without catalyst [4].

### Advent of Nanocatalysts

Nanocatalysis is an expeditiously mounting field which encompasses the use of nanomaterials as catalysts for a variety of homogeneous and heterogeneous catalysis applications. Since nanoparticles have a large surface-to-volume ratio paralleled to bulk materials, they are striking candidates for

use as catalysts (Figure 3). Nanocatalysis amalgamates the beneficial features of both homogenous and heterogeneous catalysis, however decreasing their respective shortcomings [5].

**Figure 3:** Diagram signifying types and features of nanocatalysts.

a) In homogeneous catalysis, the initial materials and the catalytic substance are brought together in the similar phase, which confirms great catalytic activity and selectivity [6]. However, the practical application of homogeneous catalysis is restricted by the complications to isolate the catalyst from the product after completion of the reaction [7].

b) In heterogeneous catalysis, the initial materials and the catalytic substance exist in different phases [8], thereby assuaging the separation of products and catalyst. However a major disadvantage of traditional heterogeneous catalyst systems when equated to their homogeneous counterparts is the curtailed surface area that is available to reactant molecules, thus restraining their catalytic activities [9] and leading to a superfluously high consumption of exclusive catalyst materials [10]. However this problem can be sorted out by increasing the surface to volume ratio (S/V) thus reducing the size of the catalytically active material [11,12].

### Dimensions for Catalytic Performance of a Nanocatalyst

The most significant objective of nanocatalysis research is to generate catalysts with maximum selectivity, enormously great activity, low energy consumption, and protracted lifetime. A nanocatalyst is considered to be preeminent if it exhibits superior performance in the ensuing dimensions:

- a. Selectivity,
- b. Activity,
- c. Durability and
- d. Recoverability

a) A catalyst should be highly selective producing 100% of the product despite the fact that the reaction pathway would result into thermodynamically stable molecules. In this way, a wearisome separation step can be removed thereby converting raw material into the product more proficiently [1].

b) The number of reactant molecules converted into product per unit time by the catalyst is expressed by the activity of catalyst which is measured using turnover frequency (TOF). As compared to homogenous catalytic systems which exhibits appropriately TOF in the range of 0.3s<sup>-1</sup> or higher, nanocatalytic systems are targeted to attain much higher TOF making it more promising for industrial applications.

c) The catalyst with high durability permits the profitable production of large amount of the product before the system could be interrupted for the catalytic replacement. The durability or lifetime of a catalyst can be measured in terms of turnover number (TON), which is actually expressed as the total amount of product (in moles) that can be formed by a given amount (in moles) of catalyst [13].

d) The foremost intrusion to the commercial application of a lot of promising homogeneous catalytic systems is the recoverability of the catalytically active substance. Hence, an optimal nanocatalyst features an intrinsic system enabling its separation from the reaction mixture and its reuse after termination of the reaction.

### Factors Affecting Catalytic Activity of Nano-catalyst

The four dimensions revealed overhead are intensely influenced by following parameters:

- Size of catalyst
- Geometry of catalyst
- Surface functionality
- Surface composition
- Aggregation attitude
- Physical environment and
- Chemical environment

### Conclusion

Nanocatalysts are part of upcoming cutting edge technology. The field of nano catalysis has endured a rapid growth during the past decade, both in homogeneous and heterogeneous catalysis. Nano particles have a large surface-to-volume ratio as equated to bulk materials; hence they are striking materials to be used as catalysts. Nanomaterials offer many possibilities as catalysts to meet future global demands in the following catalytic process technology:

- Petroleum refining
- Petrochemical industry

- Synthetic fuel production
- Polymer manufacturing
- Pharmaceutical sector
- Food processing and
- Chemical sector

Research in nanotechnology and nanoscience is expected to have a great impact on the development of new catalysts. The present article is just an overview of the nanocatalysts which are illustrated as an approach towards green chemistry contributing with lower energy consumption, longer lifetime and high selectivity. The diligent understanding of nanosized substances and the capacity to control materials on the nanometer scale will confirm a rational and cost effective expansion of new and more capable catalysts for a chemical process.
